## Revision History

The following revision history table summarizes changes contained in this document.

### Revision History

<b>Revision Number</b>	<b>Date</b>	<b>Author</b>	<b>Summary of changes</b>
v01.00	5 Feb 2004		Initial version

## List of Sections

<b>Section 1. Introduction</b> . . . . .	<b>19</b>
<b>Section 2. Overview</b> . . . . .	<b>25</b>
<b>Section 3. Addressing Modes</b> . . . . .	<b>35</b>
<b>Section 4. Instruction Queue</b> . . . . .	<b>53</b>
<b>Section 5. Instruction Set Overview</b> . . . . .	<b>61</b>
<b>Section 6. Instruction Glossary</b> . . . . .	<b>95</b>
<b>Section 7. Exception Processing</b> . . . . .	<b>405</b>
<b>Section 8. Instruction Queue</b> . . . . .	<b>419</b>
<b>Section 9. Fuzzy Logic Support</b> . . . . .	<b>433</b>
<b>Appendix A. Instruction Reference</b> . . . . .	<b>473</b>
<b>Appendix B. High-Level Language Support</b> . . . . .	<b>511</b>

# List of Sections

## Table of Contents

### Section 1. Introduction

1.1	Introduction . . . . .	19
1.2	Features . . . . .	19
1.3	Symbols and Notation . . . . .	20
1.3.1	Abbreviations for System Resources . . . . .	20
1.3.2	Memory and Addressing . . . . .	21
1.3.3	Operators . . . . .	22
1.3.4	Definitions . . . . .	23

### Section 2. Overview

2.1	Introduction . . . . .	25
2.2	Programming Model . . . . .	25
2.2.1	Accumulators . . . . .	27
2.2.2	Index Registers . . . . .	27
2.2.3	Stack Pointer . . . . .	27
2.2.4	Program Counter . . . . .	28
2.2.5	Condition Code Register . . . . .	28
2.2.5.1	IPL[2:0]. . . . .	30
2.2.5.2	S Control Bit . . . . .	30
2.2.5.3	X Mask Bit . . . . .	30
2.2.5.4	H Status Bit . . . . .	31
2.2.5.5	I Mask Bit . . . . .	32
2.2.5.6	N Status Bit . . . . .	32
2.2.5.7	Z Status Bit . . . . .	32
2.2.5.8	V Status Bit . . . . .	33
2.2.5.9	C Status Bit . . . . .	33
2.3	Data Types . . . . .	33
2.4	Memory Organization . . . . .	34
2.5	Instruction Queue . . . . .	34

**Section 3. Addressing Modes**

3.1 Introduction . . . . .35

3.2 Mode Summary . . . . .35

3.3 Effective Address . . . . .35

3.4 Inherent Addressing Mode . . . . .36

3.5 Immediate Addressing Mode . . . . .37

3.6 Direct Addressing Mode (HCS12) . . . . .38

3.7 Direct Addressing Mode (HCS12X) . . . . .38

3.8 Extended Addressing Mode . . . . .39

3.9 Relative Addressing Mode . . . . .39

3.10 Indexed Addressing Modes . . . . .40

3.10.1 5-Bit Constant Offset Indexed Addressing . . . . .43

3.10.2 9-Bit Constant Offset Indexed Addressing . . . . .43

3.10.3 16-Bit Constant Offset Indexed Addressing . . . . .44

3.10.4 16-Bit Constant Indirect Indexed Addressing . . . . .44

3.10.5 Auto Pre/Post Decrement/Increment Indexed Addressing . . . . .45

3.10.6 Accumulator Offset Indexed Addressing . . . . .46

3.10.7 Accumulator D Indirect Indexed Addressing . . . . .47

3.11 Global Addressing (HCS12X only) . . . . .48

3.12 Instructions Using Multiple Modes . . . . .48

3.12.1 Move Instructions . . . . .48

3.12.2 Bit Manipulation Instructions . . . . .49

3.13 Addressing More than 64 Kbytes . . . . .50

**Section 4. Instruction Queue**

4.1 Introduction . . . . .53

4.2 Queue Description . . . . .53

4.2.1 HCS12 and HCS12X Queue Implementation . . . . .54

4.3 Data Movement in the Queue . . . . .54

4.3.1 No Movement . . . . .54

4.3.2 Advance and Load from Data Bus . . . . .54

4.4 Changes in Execution Flow . . . . .55

4.4.1 Exceptions . . . . .55

4.4.2 Subroutines . . . . .56

4.4.3	Branches	56
4.4.3.1	Short Branches	57
4.4.3.2	Long Branches	57
4.4.3.3	Bit Condition Branches	58
4.4.3.4	Loop Primitives	58
4.4.4	Jumps	59

## Section 5. Instruction Set Overview

5.1	Introduction	61
5.2	Instruction Set Description	61
5.3	Load and Store Instructions	62
5.4	Transfer and Exchange Instructions	63
5.5	Move Instructions	65
5.6	Addition and Subtraction Instructions	66
5.7	Binary-Coded Decimal Instructions	67
5.8	Decrement and Increment Instructions	68
5.9	Compare and Test Instructions	69
5.10	Boolean Logic Instructions	70
5.11	Clear, Complement, and Negate Instructions	71
5.12	Multiplication and Division Instructions	72
5.13	Bit Test and Manipulation Instructions	73
5.14	Shift and Rotate Instructions	74
5.15	Fuzzy Logic Instructions	75
5.15.1	Fuzzy Logic Membership Instruction	75
5.15.2	Fuzzy Logic Rule Evaluation Instructions	75
5.15.3	Fuzzy Logic Weighted Average Instruction	76
5.16	Maximum and Minimum Instructions	78
5.17	Multiply and Accumulate Instruction	78
5.18	Table Interpolation Instructions	79
5.19	Branch Instructions	80
5.19.1	Short Branch Instructions	80
5.19.2	Long Branch Instructions	81
5.19.3	Bit Condition Branch Instructions	83

## Table of Contents

5.20	Loop Primitive Instructions . . . . .	84
5.21	Jump and Subroutine Instructions . . . . .	85
5.22	Interrupt Instructions . . . . .	86
5.23	Index Manipulation Instructions . . . . .	88
5.24	Stacking Instructions . . . . .	89
5.25	Pointer and Index Calculation Instructions . . . . .	90
5.26	Condition Code Instructions . . . . .	91
5.27	Stop and Wait Instructions . . . . .	92
5.28	Background Mode and Null Operations . . . . .	93

### Section 6. Instruction Glossary

6.1	Introduction . . . . .	95
6.2	Glossary Information . . . . .	95
6.3	Condition Code Changes . . . . .	97
6.4	Object Code Notation . . . . .	98
6.5	Source Forms . . . . .	99
6.6	Cycle-by-Cycle Execution . . . . .	102
6.7	Glossary . . . . .	107

### Section 7. Exception Processing

7.1	Introduction . . . . .	405
7.2	Types of Exceptions . . . . .	405
7.3	Exception Priority . . . . .	407
7.4	Resets . . . . .	409
7.4.1	Power-On Reset . . . . .	409
7.4.2	External Reset . . . . .	409
7.4.3	COP Reset . . . . .	410
7.4.4	Clock Monitor Reset . . . . .	410
7.5	Interrupts . . . . .	410
7.5.1	Non-Maskable Interrupt Request ( $\overline{XIRQ}$ ) . . . . .	<b>410</b>
7.5.2	Maskable Interrupts . . . . .	411
7.5.3	Interrupt Recognition . . . . .	411
7.5.4	External Interrupts . . . . .	412

7.5.5	Return-from-Interrupt Instruction (RTI) . . . . .	413
7.6	Unimplemented Opcode Trap . . . . .	413
7.7	Software Interrupt Instruction (SWI) . . . . .	414
7.8	Exception Processing Flow . . . . .	414
7.8.1	Vector Fetch . . . . .	414
7.8.2	Reset Exception Processing . . . . .	415
7.8.3	Interrupt and Unimplemented Opcode Trap Exception Processing . . . . .	417

## Section 8. Instruction Queue

8.1	Introduction . . . . .	419
8.2	External Reconstruction of the Queue . . . . .	419
8.3	Instruction Queue Status Signals . . . . .	420
8.3.1	HCS12 Timing Detail . . . . .	421
8.3.2	HCS12X Timing Detail . . . . .	423
8.3.3	Null . . . . .	424
8.3.4	ALD — Advance and Load from Data Bus . . . . .	425
8.3.5	INT — Interrupt Sequence Start . . . . .	425
8.3.6	SEV — Start Instruction on Even Address . . . . .	425
8.3.7	SOD — Start Instruction on Odd Address . . . . .	425
8.4	Queue Reconstruction (for HCS12) . . . . .	425
8.4.1	Queue Reconstruction Registers (for HCS12) . . . . .	426
8.4.1.1	fetch_add Register . . . . .	426
8.4.1.2	st1_add, st1_dat Registers . . . . .	427
8.4.1.3	st2_add, st2_dat Registers . . . . .	427
8.4.1.4	st3_add, st3_dat Registers . . . . .	427
8.4.2	Reconstruction Algorithm (for HCS12X) . . . . .	427
8.5	Instruction Tagging (HCS12) . . . . .	428
8.6	Instruction Tagging (HCS12X) . . . . .	430

## Section 9. Fuzzy Logic Support

9.1	Introduction . . . . .	433
9.2	Fuzzy Logic Basics . . . . .	434
9.2.1	Fuzzification (MEM) . . . . .	436
9.2.2	Rule Evaluation (REV and REVW) . . . . .	438

## Table of Contents

9.2.3	Defuzzification (WAV)	440
9.3	Example Inference Kernel	441
9.4	MEM Instruction Details	444
9.4.1	Membership Function Definitions	444
9.4.2	Abnormal Membership Function Definitions	446
9.4.2.1	Abnormal Membership Function Case 1	448
9.4.2.2	Abnormal Membership Function Case 2	449
9.4.2.3	Abnormal Membership Function Case 3	449
9.5	REV and REVW Instruction Details	450
9.5.1	Unweighted Rule Evaluation (REV)	450
9.5.1.1	Set Up Prior to Executing REV	450
9.5.1.2	Interrupt Details	452
9.5.1.3	Cycle-by-Cycle Details for REV	452
9.5.2	Weighted Rule Evaluation (REWW)	456
9.5.2.1	Set Up Prior to Executing REWW	456
9.5.2.2	Interrupt Details	458
9.5.2.3	Cycle-by-Cycle Details for REWW	458
9.6	WAV Instruction Details	461
9.6.1	Set Up Prior to Executing WAV	462
9.6.2	WAV Interrupt Details	462
9.6.3	Cycle-by-Cycle Details for WAV and wavr	463
9.7	Custom Fuzzy Logic Programming	467
9.7.1	Fuzzification Variations	467

# Section 1. Introduction

## 1.1 Introduction

This manual describes the features and operation of the central processing unit, or CPU12, used in HCS12 and HCS12X microcontrollers. 68HC12, HCS12 and HCS12X represent three generations of 16Bit Controllers with all of them being derived from the industry standard M68HC11. Detailed information for the M68HC12 is provided in the CPU12RM/AD REV 3. This document covers the HCS12 and HCS12X. The term CPU12 is used if the contents applies to both versions.

## 1.2 Features

The CPU12 is a high-speed, 16-bit processing unit that has a programming model identical to that of the industry standard M68HC11 central processor unit (CPU). The CPU12 instruction set is a proper superset of the M68HC11 instruction set, and M68HC11 source code is accepted by CPU12 assemblers with no changes.

- Full 16-bit data paths supports efficient arithmetic operation and high-speed math execution
- Supports instructions with odd byte counts, including many single-byte instructions. This allows much more efficient use of ROM space.
- An instruction queue buffers program information so the CPU12 has immediate access to at least three bytes of machine code at the start of every instruction.
- Extensive set of indexed addressing capabilities, including:
  - Using the stack pointer as an indexing register in all indexed operations

- Using the program counter as an indexing register in all but auto increment/decrement mode
- Accumulator offsets using A, B, or D accumulators
- Automatic index predecrement, preincrement, postdecrement, and postincrement (by  $-8$  to  $+8$ )

## 1.3 Symbols and Notation

The symbols and notation shown here are used throughout the manual. More specialized notation that applies only to the instruction glossary or instruction set summary are described at the beginning of those sections.

### 1.3.1 Abbreviations for System Resources

A	— Accumulator A
B	— Accumulator B
D	— Double accumulator D (A : B)
X	— Index register X
Y	— Index register Y
SP	— Stack pointer
PC	— Program counter
CCR	— Condition code register
	S — STOP instruction control bit
	X — Non-maskable interrupt control bit
	H — Half-carry status bit
	I — Maskable interrupt control bit
	N — Negative status bit
	Z — Zero status bit
	V — Two's complement overflow status bit
	C — Carry/Borrow status bit

### 1.3.2 Memory and Addressing

M	— 8-bit memory location pointed to by the effective address of the instruction
M : M+1	— 16-bit memory location. Consists of the contents of the location pointed to by the effective address concatenated with the contents of the location at the next higher memory address. The most significant byte is at location M.
M~M+3 M <sub>(Y)</sub> ~M <sub>(Y+3)</sub>	— 32-bit memory location. Consists of the contents of the effective address of the instruction concatenated with the contents of the next three higher memory locations. The most significant byte is at location M or M <sub>(Y)</sub> .
M <sub>(X)</sub>	— Memory locations pointed to by index register X
M <sub>(SP)</sub>	— Memory locations pointed to by the stack pointer
M <sub>(Y+3)</sub>	— Memory locations pointed to by index register Y plus 3
PPAGE	— Program overlay page (bank) number for extended memory (>64 Kbytes).
Page	— Program overlay page
X <sub>H</sub>	— High-order byte
X <sub>L</sub>	— Low-order byte
( )	— Content of register or memory location
\$	— Hexadecimal value
%	— Binary value

## 1.3.3 Operators

- + — Addition
- − — Subtraction
- — Logical AND
- + — Logical OR (inclusive)
- ⊕ — Logical exclusive OR
- × — Multiplication
- ÷ — Division
- $\bar{M}$  — Negation. One's complement (invert each bit of M)
- : — Concatenate  
Example: A : B means the 16-bit value formed by concatenating 8-bit accumulator A with 8-bit accumulator B. A is in the high-order position.
- ⇒ — Transfer  
Example: (A) ⇒ M means the content of accumulator A is transferred to memory location M.
- ↔ — Exchange  
Example: D ↔ X means exchange the contents of D with those of X.

### 1.3.4 Definitions

**Logic level 1** is the voltage that corresponds to the true (1) state.

**Logic level 0** is the voltage that corresponds to the false (0) state.

**Set** refers specifically to establishing logic level 1 on a bit or bits.

**Cleared** refers specifically to establishing logic level 0 on a bit or bits.

**Asserted** means that a signal is in active logic state. An active low signal changes from logic level 1 to logic level 0 when asserted, and an active high signal changes from logic level 0 to logic level 1.

**Negated** means that an asserted signal changes logic state. An active low signal changes from logic level 0 to logic level 1 when negated, and an active high signal changes from logic level 1 to logic level 0.

**ADDR** is the mnemonic for address bus.

**DATA** is the mnemonic for data bus.

**LSB** means least significant bit or bits.

**MSB** means most significant bit or bits.

**LSW** means least significant word or words.

**MSW** means most significant word or words.

**A specific bit location** within a range is referred to by mnemonic and number. For example, A7 is bit 7 of accumulator A.

**A range of bit locations** is referred to by mnemonic and the numbers that define the range. For example, DATA[15:8] form the high byte of the data bus.

# Section 2. Overview

## 2.1 Introduction

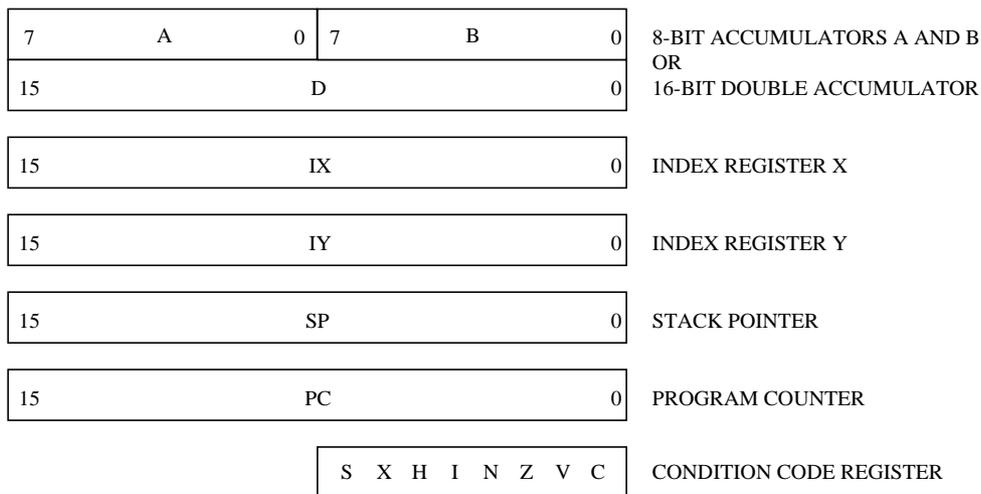

This section describes the HCS12 and the HCS12X programming model, register set, the data types used, and basic memory organization.

## 2.2 Programming Model

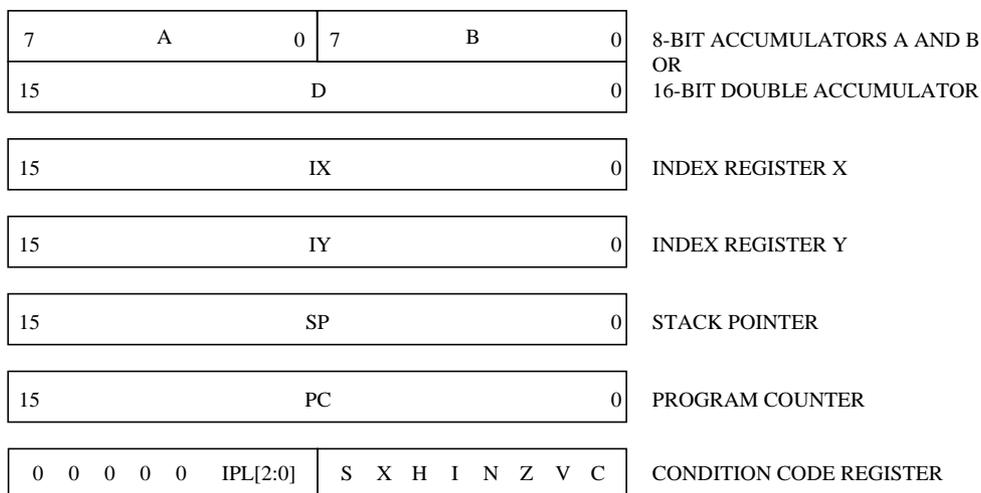

The HCS12 programming model, shown in [Figure 2-1](#), is the same as that of the M68HC11 CPU. The CPU12 has two 8-bit general-purpose accumulators (A and B) that can be concatenated into a single 16-bit accumulator (D) for certain instructions. It also has:

- Two index registers (X and Y)
- 16-bit stack pointer (SP)
- 16-bit program counter (PC)
- HCS12 - 8-bit condition code register (CCR)
- HCS12X - 16-bit condition code register (CCRW = CCRH:CCR)

The HCS12X programming model shown in [Figure 2-2](#) features a 16 Bit condition code register with the lower 8-Bit portion identical to the HCS12 version.

**Figure 2-1. HCS12 Programming Model**

**Figure 2-2. HCS12X Programming Model**

## 2.2.1 Accumulators

General-purpose 8-bit accumulators A and B are used to hold operands and results of operations. Some instructions treat the combination of these two 8-bit accumulators (A : B) as a 16-bit double accumulator (D).

Most operations can use accumulator A or B interchangeably. However, there are a few exceptions. Add, subtract, and compare instructions involving both A and B (ABA, SBA, and CBA) only operate in one direction, so it is important to make certain the correct operand is in the correct accumulator. The decimal adjust accumulator A (DAA) instruction is used after binary-coded decimal (BCD) arithmetic operations. There is no equivalent instruction to adjust accumulator B.

## 2.2.2 Index Registers

16-bit index registers X and Y are used for indexed addressing. In the indexed addressing modes, the contents of an index register are added to 5-bit, 9-bit, or 16-bit constants or to the content of an accumulator to form the effective address of the instruction operand. The second index register is especially useful for moves and in cases where operands from two separate tables are used in a calculation.

## 2.2.3 Stack Pointer

The CPU12 supports an automatic program stack. The stack is used to save system context during subroutine calls and interrupts and can also be used for temporary data storage. The stack can be located anywhere in the standard 64-Kbyte address space and can grow to any size up to the total amount of memory available in the system.

The stack pointer (SP) holds the 16-bit address of the last stack location used. Normally, the SP is initialized by one of the first instructions in an application program. The stack grows downward from the address pointed to by the SP. Each time a byte is pushed onto the stack, the stack pointer is automatically decremented, and each time a byte is pulled from the stack, the stack pointer is automatically incremented.

When a subroutine is called, the address of the instruction following the calling instruction is automatically calculated and pushed onto the stack. Normally, a return-from-subroutine (RTS) or a return-from-call (RTC)

instruction is executed at the end of a subroutine. The return instruction loads the program counter with the previously stacked return address and execution continues at that address.

When an interrupt occurs, the current instruction finishes execution. The address of the next instruction is calculated and pushed onto the stack, all the CPU12 registers are pushed onto the stack, the program counter is loaded with the address pointed to by the interrupt vector, and execution continues at that address. The stacked registers are referred to as an interrupt stack frame. The HCS12 stack frame is the same as that of the M68HC11. HCS12X stack frame has increased by one byte

**NOTE:** *These instructions can be interrupted, and they resume execution once the interrupt has been serviced:*

- *REV (fuzzy logic rule evaluation)*
- *REVV (fuzzy logic rule evaluation (weighted))*
- *WAV (weighted average)*

### 2.2.4 Program Counter

The program counter (PC) is a 16-bit register that holds the address of the next instruction to be executed. It is automatically incremented each time an instruction is fetched.

### 2.2.5 Condition Code Register

The condition code register (CCR), named for its five status indicators, contains:

- Five status indicators
- Two interrupt masking bits
- STOP instruction control bit
- Interrupt Priority Level (HCS12X only)

The status bits reflect the results of CPU12 operation as it executes instructions. The five flags are:

- Half carry (H)
- Negative (N)
- Zero (Z)
- Overflow (V)
- Carry/borrow (C)

The half-carry flag is used only for BCD arithmetic operations. The N, Z, V, and C status bits allow for branching based on the results of a previous operation.

In some architectures, only a few instructions affect condition codes, so that multiple instructions must be executed in order to load and test a variable. Since most CPU12 instructions automatically update condition codes, it is rarely necessary to execute an extra instruction for this purpose. The challenge in using the CPU12 lies in finding instructions that do not alter the condition codes. The most important of these instructions are pushes, pulls, transfers, and exchanges.

It is always a good idea to refer to an instruction set summary (see [Appendix A. Instruction Reference](#)) to check which condition codes are affected by a particular instruction.

The following paragraphs describe normal uses of the condition codes. There are other, more specialized uses. For instance, the C status bit is used to enable weighted fuzzy logic rule evaluation. Specialized usages are described in the relevant portions of this manual and in [Section 6. Instruction Glossary](#).

The HCS12X extends this condition code register to a 16-Bit wide register. The lower byte is identical to the HCS12 version. The upper byte holds three bits reflecting the current processing level. These bits allow the nesting of interrupts, blocking interrupts of a lower priority. For details on interrupt processing refer to the Interrupt Block Guide.

The upper five bits are reserved for future use and should be written to zero.

### 2.2.5.1 IPL[2:0]

The IPL bits allow the nesting of interrupts, blocking interrupts of a lower priority. The current IPL is automatically pushed to the stack by the standard interrupt stacking procedure. The new IPL is copied to the CCR from the Priority Level of the highest priority active interrupt request channel. The copying takes place when the interrupt vector is fetched. The previous IPL is automatically restored by executing the RTI instruction.

### 2.2.5.2 S Control Bit

Clearing the S bit enables the STOP instruction. Execution of a STOP instruction normally causes the on-chip oscillator to stop. This may be undesirable in some applications. If the CPU12 encounters a STOP instruction while the S bit is set, it is treated like a no-operation (NOP) instruction and continues to the next instruction. Reset sets the S bit.

### 2.2.5.3 X Mask Bit

The  $\overline{XIRQ}$  input is an updated version of the  $\overline{NMI}$  input found on earlier generations of MCUs. Non-maskable interrupts are typically used to deal with major system failures, such as loss of power. However, enabling non-maskable interrupts before a system is fully powered and initialized can lead to spurious interrupts. The X bit provides a mechanism for enabling non-maskable interrupts after a system is stable.

By default, the X bit is set to 1 during reset. As long as the X bit remains set, interrupt service requests made via the  $\overline{XIRQ}$  pin are not recognized. An instruction must clear the X bit to enable non-maskable interrupt service requests made via the  $\overline{XIRQ}$  pin. Once the X bit has been cleared to 0, software cannot reset it to 1 by writing to the CCR. The X bit is not affected by maskable interrupts.

When an  $\overline{XIRQ}$  interrupt occurs after non-maskable interrupts are enabled, both the X bit and the I bit are set automatically to prevent other interrupts from being recognized during the interrupt service routine. The mask bits are set after the registers are stacked, but before the interrupt vector is fetched.

Normally, a return-from-interrupt (RTI) instruction at the end of the interrupt service routine restores register values that were present

before the interrupt occurred. Since the CCR is stacked before the X bit is set, the RTI normally clears the X bit, and thus re-enables non-maskable interrupts. While it is possible to manipulate the stacked value of X so that X is set after an RTI, there is no software method to reset X (and disable  $\overline{XIRQ}$ ) once X has been cleared.

#### 2.2.5.4 H Status Bit

The H bit indicates a carry from accumulator A bit 3 during an addition operation. The DAA instruction uses the value of the H bit to adjust a result in accumulator A to correct BCD format. H is updated only by the add accumulator A to accumulator B (ABA), add without carry (ADD), and add with carry (ADC) instructions.

### 2.2.5.5 I Mask Bit

The I bit enables and disables maskable interrupt sources. By default, the I bit is set to 1 during reset. An instruction must clear the I bit to enable maskable interrupts. While the I bit is set, maskable interrupts can become pending and are remembered, but operation continues uninterrupted until the I bit is cleared.

When an interrupt occurs after interrupts are enabled, the I bit is automatically set to prevent other maskable interrupts during the interrupt service routine. The I bit is set after the registers are stacked, but before the first instruction in the interrupt service routine is executed.

Normally, an RTI instruction at the end of the interrupt service routine restores register values that were present before the interrupt occurred. Since the CCR is stacked before the I bit is set, the RTI normally clears the I bit, and thus re-enables interrupts. Interrupts can be re-enabled by clearing the I bit within the service routine, but implementing a nested interrupt management scheme requires great care and seldom improves system performance.

### 2.2.5.6 N Status Bit

The N bit shows the state of the MSB of the result. N is most commonly used in two's complement arithmetic, where the MSB of a negative number is 1 and the MSB of a positive number is 0, but it has other uses. For instance, if the MSB of a register or memory location is used as a status flag, the user can test status by loading an accumulator.

### 2.2.5.7 Z Status Bit

The Z bit is set when all the bits of the result are 0s. Compare instructions perform an internal implied subtraction, and the condition codes, including Z, reflect the results of that subtraction. The increment index register X (INX), decrement index register X (DEX), increment index register Y (INY), and decrement index register Y (DEY) instructions affect the Z bit and no other condition flags. These operations can only determine = (equal) and  $\neq$  (not equal).

### 2.2.5.8 V Status Bit

The V bit is set when two's complement overflow occurs as a result of an operation.

### 2.2.5.9 C Status Bit

The C bit is set when a carry occurs during addition or a borrow occurs during subtraction. The C bit also acts as an error flag for multiply and divide operations. Shift and rotate instructions operate through the C bit to facilitate multiple-word shifts.

## 2.3 Data Types

The CPU12 uses these types of data:

- Bits
- 5-bit signed integers
- 8-bit signed and unsigned integers
- 8-bit, 2-digit binary-coded decimal numbers
- 9-bit signed integers
- 16-bit signed and unsigned integers
- 16-bit effective addresses
- 32-bit signed and unsigned integers

Negative integers are represented in two's complement form.

Five-bit and 9-bit signed integers are used only as offsets for indexed addressing modes.

Sixteen-bit effective addresses are formed during addressing mode computations.

Thirty-two-bit integer dividends are used by extended division instructions. Extended multiply and extended multiply-and-accumulate instructions produce 32-bit products.

## 2.4 Memory Organization

The standard CPU12 address space is 64 Kbytes. Some HCS12 and HCS12X devices support a paged memory expansion scheme that increases the standard space by means of predefined windows in address space. The CPU12 has special instructions that support use of expanded memory.

Eight-bit values can be stored at any odd or even byte address in available memory.

Sixteen-bit values are stored in memory as two consecutive bytes; the high byte occupies the lowest address, but need not be aligned to an even boundary.

Thirty-two-bit values are stored in memory as four consecutive bytes; the high byte occupies the lowest address, but need not be aligned to an even boundary.

All input/output (I/O) and all on-chip peripherals are memory-mapped. No special instruction syntax is required to access these addresses. On-chip registers and memory typically are grouped in blocks which can be relocated within the standard 64-Kbyte address space. Refer to device documentation for specific information.

## 2.5 Instruction Queue

The CPU12 uses an instruction queue to buffer program information. The mechanism is called a queue rather than a pipeline because a typical pipelined CPU executes more than one instruction at the same time, while the CPU12 always finishes executing an instruction before beginning to execute another. Refer to [Section 4. Instruction Queue](#) for more information.

## Section 3. Addressing Modes

### 3.1 Introduction

Addressing modes determine how the central processor unit (CPU12) accesses memory locations to be operated upon. This section discusses the various modes and how they are used.

### 3.2 Mode Summary

Addressing modes are an implicit part of CPU12 instructions. Refer to [Appendix A. Instruction Reference](#) for the modes used by each instruction. All CPU12 addressing modes are shown in [Table 3-1](#).

The CPU12 uses all M68HC11 modes as well as new forms of indexed addressing. Differences between M68HC11 and M68HC12 indexed modes are described in [3.10 Indexed Addressing Modes](#). Instructions that use more than one mode are discussed in [3.12 Instructions Using Multiple Modes](#).

### 3.3 Effective Address

Each addressing mode except inherent mode generates a 16-bit effective address which is used during the memory reference portion of the instruction. Effective address computations do not require extra execution cycles.

**Table 3-1. HCS12 & HCS12X Addressing Mode Summary**

Addressing Mode	Source Format	Abbreviation	Description
Inherent	<b>INST</b> (no externally supplied operands)	INH	Operands (if any) are in CPU12 registers
Immediate	<b>INST #opr8i</b> or <b>INST #opr16i</b>	IMM	Operand is included in instruction stream 8- or 16-bit size implied by context
Direct	<b>INST opr8a</b>	DIR	Operand is the lower 8 bits of an address in the range \$0000–\$00FF
Extended	<b>INST opr16a</b>	EXT	Operand is a 16-bit address
Relative	<b>INST rel8</b> or <b>INST rel16</b>	REL	An 8-bit or 16-bit relative offset from the current pc is supplied in the instruction
Indexed (5-bit offset)	<b>INST oprx5,xysp</b>	IDX	5-bit signed constant offset from X, Y, SP, or PC
Indexed (pre-decrement)	<b>INST oprx3,-xys</b>	IDX	Auto pre-decrement x, y, or sp by 1 ~ 8
Indexed (pre-increment)	<b>INST oprx3,+xys</b>	IDX	Auto pre-increment x, y, or sp by 1 ~ 8
Indexed (post-decrement)	<b>INST oprx3,xys-</b>	IDX	Auto post-decrement x, y, or sp by 1 ~ 8
Indexed (post-increment)	<b>INST oprx3,xys+</b>	IDX	Auto post-increment x, y, or sp by 1 ~ 8
Indexed (accumulator offset)	<b>INST abd,xysp</b>	IDX	Indexed with 8-bit (A or B) or 16-bit (D) accumulator offset from X, Y, SP, or PC
Indexed (9-bit offset)	<b>INST oprx9,xysp</b>	IDX1	9-bit signed constant offset from X, Y, SP, or PC (lower 8 bits of offset in one extension byte)
Indexed (16-bit offset)	<b>INST oprx16,xysp</b>	IDX2	16-bit constant offset from X, Y, SP, or PC (16-bit offset in two extension bytes)
Indexed-Indirect (16-bit offset)	<b>INST [opr16,xysp]</b>	[IDX2]	Pointer to operand is found at... 16-bit constant offset from X, Y, SP, or PC (16-bit offset in two extension bytes)
Indexed-Indirect (D accumulator offset)	<b>INST [D,xysp]</b>	[D,IDX]	Pointer to operand is found at... X, Y, SP, or PC plus the value in D

## 3.4 Inherent Addressing Mode

Instructions that use this addressing mode either have no operands or all operands are in internal CPU12 registers. In either case, the CPU12

does not need to access any memory locations to complete the instruction.

Examples:

```
NOP      ;this instruction has no operands
INX     ;operand is a CPU12 register
```

### 3.5 Immediate Addressing Mode

Operands for immediate mode instructions are included in the instruction stream and are fetched into the instruction queue one 16-bit word at a time during normal program fetch cycles. Since program data is read into the instruction queue several cycles before it is needed, when an immediate addressing mode operand is called for by an instruction, it is already present in the instruction queue.

The pound symbol (#) is used to indicate an immediate addressing mode operand. One common programming error is to accidentally omit the # symbol. This causes the assembler to misinterpret the expression that follows it as an address rather than explicitly provided data. For example, LDAA #\$55 means to load the immediate value \$55 into the A accumulator, while LDAA \$55 means to load the value from address \$0055 into the A accumulator. Without the # symbol, the instruction is erroneously interpreted as a direct addressing mode instruction.

Examples:

```
LDAA     #$55
LDX      #$1234
LDY      #$67
```

These are common examples of 8-bit and 16-bit immediate addressing modes. The size of the immediate operand is implied by the instruction context. In the third example, the instruction implies a 16-bit immediate value but only an 8-bit value is supplied. In this case the assembler will generate the 16-bit value \$0067 because the CPU12 expects a 16-bit value in the instruction stream.

Example:

```
BRSET    FOO,#$03,THERE
```

In this example, extended addressing mode is used to access the operand FOO, immediate addressing mode is used to access the mask value \$03, and relative addressing mode is used to identify the destination address of a branch in case the branch-taken conditions are

met. BRSET is listed as an extended mode instruction even though immediate and relative modes are also used.

### 3.6 Direct Addressing Mode (HCS12)

This addressing mode is sometimes called zero-page addressing because it is used to access operands in the address range \$0000 through \$00FF. Since these addresses always begin with \$00, only the eight low-order bits of the address need to be included in the instruction, which saves program space and execution time. A system can be optimized by placing the most commonly accessed data in this area of memory. The eight low-order bits of the operand address are supplied with the instruction, and the eight high-order bits of the address are assumed to be 0.

Example:

```
LDAA          $55
```

This is a basic example of direct addressing. The value \$55 is taken to be the low-order half of an address in the range \$0000 through \$00FF. The high order half of the address is assumed to be 0. During execution of this instruction, the CPU12 combines the value \$55 from the instruction with the assumed value of \$00 to form the address \$0055, which is then used to access the data to be loaded into accumulator A.

Example:

```
LDX          $20
```

In this example, the value \$20 is combined with the assumed value of \$00 to form the address \$0020. Since the LDX instruction requires a 16-bit value, a 16-bit word of data is read from addresses \$0020 and \$0021. After execution of this instruction, the X index register will have the value from address \$0020 in its high-order half and the value from address \$0021 in its low-order half.

### 3.7 Direct Addressing Mode (HCS12X)

The Direct Page Register (DIRECT) (refer to Memory Controller Block Guide) determines the position of the direct page within the memory map. The direct addressing mode is based to access operands in the address range \$00 through \$FF in the direct page. Since these

addresses always begin with the contents of the DIRECT register, only the eight low-order bits of the address need to be included in the instruction, which saves program space and execution time. A system can be optimized by placing the most commonly accessed data in this area of memory. The eight low-order bits of the operand address are supplied with the instruction, and the eight high-order bits of the address are assumed to be DIRECT.

### 3.8 Extended Addressing Mode

In this addressing mode, the full 16-bit address of the memory location to be operated on is provided in the instruction. This addressing mode can be used to access any location in the 64-Kbyte memory map.

Example:

```
LDA    $F03B
```

This is a basic example of extended addressing. The value from address \$F03B is loaded into the A accumulator.

### 3.9 Relative Addressing Mode

The relative addressing mode is used only by branch instructions. Short and long conditional branch instructions use relative addressing mode exclusively, but branching versions of bit manipulation instructions (branch if bits set (BRSET) and branch if bits cleared (BRCLR)) use multiple addressing modes, including relative mode. Refer to [3.12 Instructions Using Multiple Modes](#) for more information.

Short branch instructions consist of an 8-bit opcode and a signed 8-bit offset contained in the byte that follows the opcode. Long branch instructions consist of an 8-bit prebyte, an 8-bit opcode, and a signed 16-bit offset contained in the two bytes that follow the opcode.

Each conditional branch instruction tests certain status bits in the condition code register. If the bits are in a specified state, the offset is added to the address of the next memory location after the offset to form an effective address, and execution continues at that address. If the bits are not in the specified state, execution continues with the instruction immediately following the branch instruction.

Bit-condition branches test whether bits in a memory byte are in a specific state. Various addressing modes can be used to access the memory location. An 8-bit mask operand is used to test the bits. If each bit in memory that corresponds to a 1 in the mask is either set (BRSET) or clear (BRCLR), an 8-bit offset is added to the address of the next memory location after the offset to form an effective address, and execution continues at that address. If all the bits in memory that correspond to a 1 in the mask are not in the specified state, execution continues with the instruction immediately following the branch instruction.

8-bit, 9-bit, and 16-bit offsets are signed two's complement numbers to support branching upward and downward in memory. The numeric range of short branch offset values is \$80 (–128) to \$7F (127). Loop primitive instructions support a 9-bit offset which allows a range of \$100 (–256) to \$0FF (255). The numeric range of long branch offset values is \$8000 (–32,768) to \$7FFF (32,767). If the offset is 0, the CPU12 executes the instruction immediately following the branch instruction, regardless of the test involved.

Since the offset is at the end of a branch instruction, using a negative offset value can cause the program counter (PC) to point to the opcode and initiate a loop. For instance, a branch always (BRA) instruction consists of two bytes, so using an offset of \$FE sets up an infinite loop; the same is true of a long branch always (LBRA) instruction with an offset of \$FFFC.

An offset that points to the opcode can cause a bit-condition branch to repeat execution until the specified bit condition is satisfied. Since bit-condition branches can consist of four, five, or six bytes depending on the addressing mode used to access the byte in memory, the offset value that sets up a loop can vary. For instance, using an offset of \$FC with a BRCLR that accesses memory using an 8-bit indexed postbyte sets up a loop that executes until all the bits in the specified memory byte that correspond to 1s in the mask byte are cleared.

### 3.10 Indexed Addressing Modes

The CPU12 uses redefined versions of M68HC11 indexed modes that reduce execution time and eliminate code size penalties for using the Y index register. In most cases, CPU12 code size for indexed operations

is the same or is smaller than that for the M68HC11. Execution time is shorter in all cases. Execution time improvements are due to both a reduced number of cycles for all indexed instructions and to faster system clock speed.

The indexed addressing scheme uses a postbyte plus zero, one, or two extension bytes after the instruction opcode. The postbyte and extensions do the following tasks:

1. Specify which index register is used
2. Determine whether a value in an accumulator is used as an offset
3. Enable automatic pre- or post-increment or pre- or post-decrement
4. Specify size of increment or decrement
5. Specify use of 5-, 9-, or 16-bit signed offsets

This approach eliminates the differences between X and Y register use while dramatically enhancing the indexed addressing capabilities.

Major advantages of the CPU12 indexed addressing scheme are:

- The stack pointer can be used as an index register in all indexed operations.
- The program counter can be used as an index register in all but autoincrement and autodecrement modes.
- A, B, or D accumulators can be used for accumulator offsets.
- Automatic pre- or post-increment or pre- or post-decrement by  $-8$  to  $+8$
- A choice of 5-, 9-, or 16-bit signed constant offsets
- Use of two new indexed-indirect modes:
  - Indexed-indirect mode with 16-bit offset
  - Indexed-indirect mode with accumulator D offset

**Table 3-2** is a summary of indexed addressing mode capabilities and a description of postbyte encoding. The postbyte is noted as *xb* in instruction descriptions. Detailed descriptions of the indexed addressing mode variations follow the table.

All indexed addressing modes use a 16-bit CPU12 register and additional information to create an effective address. In most cases the

## Addressing Modes

effective address specifies the memory location affected by the operation. In some variations of indexed addressing, the effective address specifies the location of a value that points to the memory location affected by the operation.

**Table 3-2. Summary of Indexed Operations**

Postbyte Code (xb)	Source Code Syntax	Comments rr; 00 = X, 01 = Y, 10 = SP, 11 = PC
rr0nnnnn	,r n,r -n,r	<b>5-bit constant offset</b> n = -16 to +15 r can specify X, Y, SP, or PC
111rr0zs	n,r -n,r	<b>Constant offset</b> (9- or 16-bit signed) z=0 = 9-bit with sign in LSB of postbyte(s) $-256 \leq n \leq 255$ 1 = 16-bit $-32,768 \leq n \leq 65,535$ if z = s = 1, 16-bit offset indexed-indirect (see below) r can specify X, Y, SP, or PC
111rr011	[n,r]	<b>16-bit offset indexed-indirect</b> rr can specify X, Y, SP, or PC $-32,768 \leq n \leq 65,535$

111rr1aa	A,r B,r D,r	<b>Accumulator offset</b> (unsigned 8-bit or 16-bit) aa-00 = A 01 = B 10 = D (16-bit) 11 = see accumulator D offset indexed-indirect r can specify X, Y, SP, or PC
111rr111	[D,r]	<b>Accumulator D offset indexed-indirect</b> r can specify X, Y, SP, or PC

Indexed addressing mode instructions use a postbyte to specify index registers (X and Y), stack pointer (SP), or program counter (PC) as the base index register and to further classify the way the effective address is formed. A special group of instructions cause this calculated effective address to be loaded into an index register for further calculations:

- Load stack pointer with effective address (LEAS)
- Load X with effective address (LEAX)
- Load Y with effective address (LEAY)

### 3.10.1 5-Bit Constant Offset Indexed Addressing

This indexed addressing mode uses a 5-bit signed offset which is included in the instruction postbyte. This short offset is added to the base index register (X, Y, SP, or PC) to form the effective address of the memory location that will be affected by the instruction. This gives a range of -16 through +15 from the value in the base index register. Although other indexed addressing modes allow 9- or 16-bit offsets, those modes also require additional extension bytes in the instruction for this extra information. The majority of indexed instructions in real programs use offsets that fit in the shortest 5-bit form of indexed addressing.

Examples:

LDA	0,X
STAB	-8,Y

For these examples, assume X has a value of \$1000 and Y has a value of \$2000 before execution. The 5-bit constant offset mode does not change the value in the index register, so X will still be \$1000 and Y will still be \$2000 after execution of these instructions. In the first example, A will be loaded with the value from address \$1000. In the second example, the value from the B accumulator will be stored at address \$1FF8 (\$2000 - \$8).

### 3.10.2 9-Bit Constant Offset Indexed Addressing

This indexed addressing mode uses a 9-bit signed offset which is added to the base index register (X, Y, SP, or PC) to form the effective address of the memory location affected by the instruction. This gives a range of -256 through +255 from the value in the base index register. The most

significant bit (sign bit) of the offset is included in the instruction postbyte and the remaining eight bits are provided as an extension byte after the instruction postbyte in the instruction flow.

Examples:

LDAA	\$FF,X
LDAB	-20,Y

For these examples, assume X is \$1000 and Y is \$2000 before execution of these instructions.

**NOTE:** *These instructions do not alter the index registers so they will still be \$1000 and \$2000, respectively, after the instructions.*

The first instruction will load A with the value from address \$10FF and the second instruction will load B with the value from address \$1FEC.

This variation of the indexed addressing mode in the CPU12 is similar to the M68HC11 indexed addressing mode, but is functionally enhanced. The M68HC11 CPU provides for unsigned 8-bit constant offset indexing from X or Y, and use of Y requires an extra instruction byte and thus, an extra execution cycle. The 9-bit signed offset used in the CPU12 covers the same range of positive offsets as the M68HC11, and adds negative offset capability. The CPU12 can use X, Y, SP, or PC as the base index register.

### 3.10.3 16-Bit Constant Offset Indexed Addressing

This indexed addressing mode uses a 16-bit offset which is added to the base index register (X, Y, SP, or PC) to form the effective address of the memory location affected by the instruction. This allows access to any address in the 64-Kbyte address space. Since the address bus and the offset are both 16 bits, it does not matter whether the offset value is considered to be a signed or an unsigned value (\$FFFF may be thought of as +65,535 or as -1). The 16-bit offset is provided as two extension bytes after the instruction postbyte in the instruction flow.

### 3.10.4 16-Bit Constant Indirect Indexed Addressing

This indexed addressing mode adds a 16-bit instruction-supplied offset to the base index register to form the address of a memory location that contains a pointer to the memory location affected by the instruction. The

instruction itself does not point to the address of the memory location to be acted upon, but rather to the location of a pointer to the address to be acted on. The square brackets distinguish this addressing mode from 16-bit constant offset indexing.

Example:

LDAA                    [10,X]

In this example, X holds the base address of a table of pointers. Assume that X has an initial value of \$1000, and that the value \$2000 is stored at addresses \$100A and \$100B. The instruction first adds the value 10 to the value in X to form the address \$100A. Next, an address pointer (\$2000) is fetched from memory at \$100A. Then, the value stored in location \$2000 is read and loaded into the A accumulator.

### 3.10.5 Auto Pre/Post Decrement/Increment Indexed Addressing

This indexed addressing mode provides four ways to automatically change the value in a base index register as a part of instruction execution. The index register can be incremented or decremented by an integer value either before or after indexing takes place. The base index register may be X, Y, or SP. (Auto-modify modes would not make sense on PC.)

Pre-decrement and pre-increment versions of the addressing mode adjust the value of the index register before accessing the memory location affected by the instruction — the index register retains the changed value after the instruction executes. Post-decrement and post-increment versions of the addressing mode use the initial value in the index register to access the memory location affected by the instruction, then change the value of the index register.

The CPU12 allows the index register to be incremented or decremented by any integer value in the ranges  $-8$  through  $-1$  or  $1$  through  $8$ . The value need not be related to the size of the operand for the current instruction. These instructions can be used to incorporate an index adjustment into an existing instruction rather than using an additional instruction and increasing execution time. This addressing mode is also used to perform operations on a series of data structures in memory.

When an LEAS, LEAX, or LEAY instruction is executed using this addressing mode, and the operation modifies the index register that is being loaded, the final value in the register is the value that would have

been used to access a memory operand. (Premodification is seen in the result but postmodification is not.)

Examples:

STAA	1,-SP	;equivalent to PSHA
STX	2,-SP	;equivalent to PSHX
LDX	2,SP+	;equivalent to PULX
LDAA	1,SP+	;equivalent to PULA

For a “last-used” type of stack like the CPU12 stack, these four examples are equivalent to common push and pull instructions.

For a “next-available” stack like the M68HC11 stack, push A onto stack (PSHA) is equivalent to store accumulator A (STAA) 1,SP– and pull A from stack (PULA) is equivalent to load accumulator A (LDAA) 1,+SP. However, in the M68HC11, 16-bit operations like push register X onto stack (PSHX) and pull register X from stack (PULX) require multiple instructions to decrement the SP by one, then store X, then decrement SP by one again.

In the STAA 1,-SP example, the stack pointer is pre-decremented by one and then A is stored to the address contained in the stack pointer. Similarly the LDX 2,SP+ first loads X from the address in the stack pointer, then post-increments SP by two.

Example:

```
MOVW          2,X+,4,+Y
```

This example demonstrates how to work with data structures larger than bytes and words. With this instruction in a program loop, it is possible to move words of data from a list having one word per entry into a second table that has four bytes per table element. In this example the source pointer is updated after the data is read from memory (post-increment) while the destination pointer is updated before it is used to access memory (pre-increment).

### 3.10.6 Accumulator Offset Indexed Addressing

In this indexed addressing mode, the effective address is the sum of the values in the base index register and an unsigned offset in one of the accumulators. The value in the index register itself is not changed. The index register can be X, Y, SP, or PC and the accumulator can be either of the 8-bit accumulators (A or B) or the 16-bit D accumulator.

Example:

```
LDA A, [B,X]
```

This instruction internally adds B to X to form the address from which A will be loaded. B and X are not changed by this instruction. This example is similar to the following 2-instruction combination in an M68HC11.

Examples:

```
ABX
LDA A, [0,X]
```

However, this 2-instruction sequence alters the index register. If this sequence was part of a loop where B changed on each pass, the index register would have to be reloaded with the reference value on each loop pass. The use of LDA A, [B,X] is more efficient in the CPU12.

### 3.10.7 Accumulator D Indirect Indexed Addressing

This indexed addressing mode adds the value in the D accumulator to the value in the base index register to form the address of a memory location that contains a pointer to the memory location affected by the instruction. The instruction operand does not point to the address of the memory location to be acted upon, but rather to the location of a pointer to the address to be acted upon. The square brackets distinguish this addressing mode from D accumulator offset indexing.

Examples:

```
JMP [D,PC]
GO1 DC.W PLACE1
GO2 DC.W PLACE2
GO3 DC.W PLACE3
```

This example is a computed GOTO. The values beginning at GO1 are addresses of potential destinations of the jump (JMP) instruction. At the time the JMP [D,PC] instruction is executed, PC points to the address GO1, and D holds one of the values \$0000, \$0002, or \$0004 (determined by the program some time before the JMP).

Assume that the value in D is \$0002. The JMP instruction adds the values in D and PC to form the address of GO2. Next the CPU12 reads the address PLACE2 from memory at GO2 and jumps to PLACE2. The locations of PLACE1 through PLACE3 were known at the time of program assembly but the destination of the JMP depends upon the value in D computed during program execution.

### 3.11 Global Addressing (HCS12X only)

The HCS12 Core architecture limits the physical address space available to 64K bytes  $\text{addr}[15:0]$ . The HCS12X core architecture with the usage of the Global Page Index Register (refer to Memory Controller Block Guide) allows for integrating up to 8 Mbyte of memory  $\text{addr}[22:0]$  by using the seven global page index bits to page 64K byte blocks into the memory map  $\text{addr}[22:0]$  is a result of concatenation between GPAGE and  $\text{addr}[15:0]$ .

New instructions started with the label G are created for this usage like (**GLDAA**, **GSTAA**,...).

**GLDAA** : (G(M)  $\Rightarrow$  A) Load Accumulator A from Global Memory

**GLDAA** has the same addressing mode style like LDAA with the only difference is the memory address (64 KBytes) is presented by the Global memory address (8 MBytes)

This is the case for all Global instructions.

### 3.12 Instructions Using Multiple Modes

Several CPU12 instructions use more than one addressing mode in the course of execution.

#### 3.12.1 Move Instructions

Move instructions use separate addressing modes to access the source and destination of a move. There are move variations for all practical combinations of immediate, extended, and indexed addressing modes.

The only combinations of addressing modes that are not allowed are those with an immediate mode destination (the operand of an immediate mode instruction is data, not an address). For indexed moves, the reference index register may be X, Y, SP, or PC.

In the HCS12 Move instructions do not support indirect modes, 9-bit, or 16-bit offset modes requiring extra extension bytes, while the HCS12X features all addressing modes for the source operand as well as for the destination operand. There are special considerations when using PC-relative addressing with move instructions.

PC-relative addressing uses the address of the location immediately following the last byte of object code for the current instruction as a reference point. The CPU12 normally corrects for queue offset and for instruction alignment so that queue operation is transparent to the user. However, in the HCS12X, move instructions using PC relative addressing pose a special problem:

- Some moves have object code that is too long to fit in the queue all at one time, so the PC value changes during execution.

This case is not handled by automatic queue pointer maintenance, but it is still possible to use PC-relative indexing with move instructions by providing for PC offsets in source code.

A PC offset must be applied to the source address when using PC relative index addressing for the source operand and any of the three destination index addressing modes listed below:

IDX1: +1

IDX2: +2

[IDX2]: +2

These offsets compensate for the variable instruction length and are needed to identify the location of the instruction immediately following the MOVB/MOVW instruction.

### 3.12.2 Bit Manipulation Instructions

Bit manipulation instructions use either a combination of two or a combination of three addressing modes.

The clear bits in memory (BCLR) and set bits in memory (BSET) instructions use an 8-bit mask to determine which bits in a memory byte are to be changed. The mask must be supplied with the instruction as an immediate mode value. The memory location to be modified can be specified by means of direct, extended, or indexed addressing modes.

The BTAS (Bit Test And Set) works by starting to test bits in memory location M, then set bits in memory location M. To test then set a bit, set the corresponding bit in the mask byte. All other bits in M are unchanged.

BTAS is an atomic instruction and may be used to implement a semaphore.

The branch if bits cleared (BRCLR) and branch if bits set (BRSET) instructions use an 8-bit mask to test the states of bits in a memory byte. The mask is supplied with the instruction as an immediate mode value. The memory location to be tested is specified by means of direct, extended, or indexed addressing modes. Relative addressing mode is used to determine the branch address. A signed 8-bit offset must be supplied with the instruction.

### 3.13 Addressing More than 64 Kbytes

Some HCS12 and HCS12X devices incorporate hardware that supports addressing a larger memory space than the standard 64 Kbytes. The expanded memory system uses fast on-chip logic to implement a transparent bank-switching scheme ([3.11 Global Addressing \(HCS12X only\)](#)).

Increased code efficiency is the greatest advantage of using a switching scheme instead of a large linear address space. In systems with large linear address spaces, instructions require more bits of information to address a memory location, and CPU12 overhead is greater. Other advantages include the ability to change the size of system memory and the ability to use various types of external memory.

However, the add-on bank switching schemes used in other microcontrollers have known weaknesses. These include the cost of external glue logic, increased programming overhead to change banks, and the need to disable interrupts while banks are switched.

The HCS12 and HCS12X systems requires no external glue logic. Bank switching overhead is reduced by implementing control logic in the MCU. Interrupts do not need to be disabled during switching because switching tasks are incorporated in special instructions that greatly simplify program access to extended memory.

MCUs with expanded memory treat the 16 Kbytes of memory space from \$8000 to \$BFFF as a program memory window. Expanded-memory architecture includes an 8-bit program page register (PPAGE), which allows up to 256 16-Kbyte program memory pages to

be switched into and out of the program memory window. This provides for up to 4 Megabytes of paged program memory.

The CPU12 instruction set includes call subroutine in expanded memory (CALL) and return from call (RTC) instructions, which greatly simplify the use of expanded memory space. These instructions also execute correctly on devices that do not have expanded-memory addressing capability, thus providing for portable code.

The CALL instruction is similar to the jump-to-subroutine (JSR) instruction. When CALL is executed, the current value in PPAGE is pushed onto the stack with a return address, and a new instruction-supplied value is written to PPAGE. This value selects the page the called subroutine resides upon and can be considered part of the effective address. For all addressing mode variations except indexed indirect modes, the new page value is provided by an immediate operand in the instruction. For indexed indirect variations of CALL, a pointer specifies memory locations where the new page value and the address of the called subroutine are stored. Use of indirect addressing for both the page value and the address within the page frees the program from keeping track of explicit values for either address.

The RTC instruction restores the saved program page value and the return address from the stack. This causes execution to resume at the next instruction after the original CALL instruction.

See specific SoC Guide for more information on the memory layout of the particular device.

## Section 4. Instruction Queue

### 4.1 Introduction

The CPU12 uses an instruction queue to increase execution speed. This section describes queue operation during normal program execution and changes in execution flow. These concepts augment the descriptions of instructions and cycle-by-cycle instruction execution in subsequent sections, but it is important to note that queue operation is automatic, and generally transparent to the user.

The material in this section is general. [Section 6. Instruction Glossary](#) contains detailed information concerning cycle-by-cycle execution of each instruction. [Section 8. Instruction Queue](#) contains detailed information about tracking queue operation and instruction execution.

### 4.2 Queue Description

The fetching mechanism in the CPU12 is best described as a queue rather than as a pipeline. Queue logic fetches program information and positions it for execution, but instructions are executed sequentially. A typical pipelined central processor unit (CPU12) can execute more than one instruction at the same time, but interactions between the prefetch and execution mechanisms can make tracking and debugging difficult. The CPU12 thus gains the advantages of independent fetches, yet maintains a straightforward relationship between bus and execution cycles.

Each instruction refills the queue by fetching the same number of bytes that the instruction uses. Program information is fetched in aligned 16-bit words. Each program fetch (P) indicates that two bytes need to be replaced in the instruction queue. Each optional fetch (O) indicates that only one byte needs to be replaced. For example, an instruction composed of five bytes does two program fetches and one optional fetch. If the first byte of the five-byte instruction was even-aligned, the

optional fetch is converted into a free cycle. If the first byte was odd-aligned, the optional fetch is executed as a program fetch.

External pins, like IPIPE[1:0] for HCS12 and IQSTAT[3:0] for HCS12X, provide information about data movement in the queue and instruction execution. Decoding and use of these signals is discussed in [Section 8. Instruction Queue](#).

### 4.2.1 HCS12 and HCS12X Queue Implementation

There are three 16-bit stages in the instruction queue. Instructions enter the queue at stage 1 and shift out of stage 3 as the CPU12 executes instructions and fetches new ones into stage 1. Each byte in the queue is selectable. An opcode prediction algorithm determines the location of the next opcode in the instruction queue.

## 4.3 Data Movement in the Queue

All queue operations are combinations of two basic queue movement cycles. Descriptions of each of these cycles follows. Queue movement cycles are only one factor in instruction execution time and should not be confused with bus cycles.

### 4.3.1 No Movement

There is no data movement in the instruction queue during the cycle. This occurs during execution of instructions that must perform a number of internal operations, such as division instructions.

### 4.3.2 Advance and Load from Data Bus

The content of queue is advanced by one stage, and stage 1 is loaded with a word of program information from the data bus. The information was requested two bus cycles earlier but has only become available this cycle, due to access delay.

## 4.4 Changes in Execution Flow

During normal instruction execution, queue operations proceed as a continuous sequence of queue movement cycles. However, situations arise which call for changes in flow. These changes are categorized as resets, interrupts, subroutine calls, conditional branches, and jumps. Generally speaking, resets and interrupts are considered to be related to events outside the current program context that require special processing, while subroutine calls, branches, and jumps are considered to be elements of program structure.

During design, great care is taken to assure that the mechanism that increases instruction throughput during normal program execution does not cause bottlenecks during changes of program flow, but internal queue operation is largely transparent to the user. The following information is provided to enhance subsequent descriptions of instruction execution.

### 4.4.1 Exceptions

Exceptions are events that require processing outside the normal flow of instruction execution. CPU12 exceptions include five types of exceptions:

- Reset (including COP, clock monitor, and pin)
- Unimplemented opcode trap
- Software interrupt instruction
- X-bit interrupts
- I-bit interrupts

All exceptions use the same microcode, but the CPU12 follows different execution paths for each type of exception.

CPU12 exception handling is designed to minimize the effect of queue operation on context switching. Thus, an exception vector fetch is the first part of exception processing, and fetches to refill the queue from the address pointed to by the vector are interleaved with the stacking operations that preserve context, so that program access time does not delay the switch. Refer to [Section 7. Exception Processing](#) for detailed information.

### 4.4.2 Subroutines

The CPU12 can branch to (BSR), jump to (JSR), or call (CALL) subroutines. BSR and JSR are used to access subroutines in the normal 64-Kbyte address space. The CALL instruction is intended for use in MCUs with expanded memory capability.

BSR uses relative addressing mode to generate the effective address of the subroutine, while JSR can use various other addressing modes. Both instructions calculate a return address, stack the address, then perform three program word fetches to refill the queue.

Subroutines in the normal 64-Kbyte address space are terminated with a return-from-subroutine (RTS) instruction. RTS unstacks the return address, then performs three program word fetches from that address to refill the queue.

CALL is similar to JSR. MCUs with expanded memory treat 16 Kbytes of addresses from \$8000 to \$BFFF as a memory window. An 8-bit PPAGE register switches memory pages into and out of the window. When CALL is executed, a return address is calculated, then it and the current PPAGE value are stacked, and a new instruction-supplied value is written to PPAGE. The subroutine address is calculated, then three program word fetches are made from that address to refill the instruction queue.

The return-from-call (RTC) instruction is used to terminate subroutines in expanded memory. RTC unstacks the PPAGE value and the return address, then performs three program word fetches from that address to refill the queue.

CALL and RTC execute correctly in the normal 64-Kbyte address space, thus providing for portable code. However, since extra execution cycles are required, routinely substituting CALL/RTC for JSR/RTS is not recommended.

### 4.4.3 Branches

Branch instructions cause execution flow to change when specific pre-conditions exist. The CPU12 instruction set includes:

- Short conditional branches

- Long conditional branches
- Bit-condition branches

Types and conditions of branch instructions are described in [5.19 Branch Instructions](#). All branch instructions affect the queue similarly, but there are differences in overall cycle counts between the various types. Loop primitive instructions are a special type of branch instruction used to implement counter-based loops.

Branch instructions have two execution cases:

- The branch condition is satisfied, and a change of flow takes place.
- The branch condition is not satisfied, and no change of flow occurs.

#### 4.4.3.1 Short Branches

The “not-taken” case for short branches is simple. Since the instruction consists of a single word containing both an opcode and an 8-bit offset, the queue advances, another program word is fetched, and execution continues with the next instruction.

The “taken” case for short branches requires that the queue be refilled so that execution can continue at a new address. First, the effective address of the destination is calculated using the relative offset in the instruction. Then, the address is loaded into the program counter, and the CPU12 performs three program word fetches at the new address to refill the instruction queue.

#### 4.4.3.2 Long Branches

The “not-taken” case for all long branches requires three cycles, while the “taken” case requires four cycles. This is due to differences in the amount of program information needed to fill the queue.

Long branch instructions begin with a \$18 prebyte which indicates that the opcode is on page 2 of the opcode map. The CPU12 treats the prebyte as a special one-byte instruction. If the prebyte is not aligned, the first cycle is used to perform a program word access; if the prebyte is aligned, the first cycle is used to perform a free cycle. The first cycle for the prebyte is executed whether or not the branch is taken.

The first cycle of the branch instruction is an optional cycle. Optional cycles make the effects of byte-sized and misaligned instructions consistent with those of aligned word-length instructions. Program information is always fetched as aligned 16-bit words. When an instruction has an odd number of bytes, and the first byte is not aligned with an even byte boundary, the optional cycle makes an additional program word access that maintains queue order. In all other cases, the optional cycle is a free cycle.

In the “not-taken” case, the queue must advance so that execution can continue with the next instruction. Two cycles are used to refill the queue. Alignment determines how the second of these cycles is used.

In the “taken” case, the effective address of the branch is calculated using the 16-bit relative offset contained in the second word of the instruction. This address is loaded into the program counter, then the CPU12 performs three program word fetches at the new address.

### 4.4.3.3 Bit Condition Branches

Bit condition branch instructions read a location in memory, and branch if the bits in that location are in a certain state. These instructions can use direct, extended, or indexed addressing modes. Indexed operations require varying amounts of information to determine the effective address, so instruction length varies according to the mode used, which in turn affects the amount of program information fetched. To shorten execution time, these branches perform one program word fetch in anticipation of the “taken” case. The data from this fetch is ignored in the “not-taken” case. If the branch is taken, the CPU12 fetches three program word fetches at the new address to fill the instruction queue.

### 4.4.3.4 Loop Primitives

The loop primitive instructions test a counter value in a register or accumulator and branch to an address specified by a 9-bit relative offset contained in the instruction if a specified condition is met. There are auto-increment and auto-decrement versions of these instructions. The test and increment/decrement operations are performed on internal CPU12 registers, and require no additional program information. To shorten execution time, these branches perform one program word fetch in anticipation of the “taken” case. The data from this fetch is ignored if the branch is not taken, and the CPU12 does one program fetch and one

optional fetch to refill the queue<sup>1</sup>. If the branch is taken, the CPU12 finishes refilling the queue with two additional program word fetches at the new address.

#### 4.4.4 Jumps

Jump (JMP) is the simplest change of flow instruction. JMP can use extended or indexed addressing. Indexed operations require varying amounts of information to determine the effective address, so instruction length varies according to the mode used, which in turn affects the amount of program information fetched. All forms of JMP perform three program word fetches at the new address to refill the instruction queue.

---

1. In the original M68HC12, the implementation of these two cycles are both program word fetches.

## Section 5. Instruction Set Overview

### 5.1 Introduction

This section contains general information about the central processor unit (CPU12) instruction set. It is organized into instruction categories grouped by function.

### 5.2 Instruction Set Description

CPU12 instructions are a superset of the M68HC11 instruction set. Code written for an M68HC11 can be reassembled and run on a CPU12 with no changes. The CPU12 provides expanded functionality and increased code efficiency. There are two implementations of the CPU12, the original M68HC12 and the newer HCS12X. Both implementations have the same instruction set, although there are small differences in cycle-by-cycle access details (the order of some bus cycles changed to accommodate differences in the way the instruction queue was implemented). These minor differences are transparent for most users.

In the M68HC12 and HCS12X architecture, all memory and input/output (I/O) are mapped in a common 64-Kbyte address space (memory-mapped I/O). This allows the same set of instructions to be used to access memory, I/O, and control registers. General-purpose load, store, transfer, exchange, and move instructions facilitate movement of data to and from memory and peripherals.

The CPU12 has a full set of 8-bit and 16-bit mathematical instructions. There are instructions for signed and unsigned arithmetic, division, and multiplication with 8-bit, 16-bit, and some larger operands.

Special arithmetic and logic instructions aid stacking operations, indexing, binary-coded decimal (BCD) calculation, and condition code register manipulation. There are also dedicated instructions for multiply and accumulate operations, table interpolation, and specialized fuzzy logic operations that involve mathematical calculations.

Refer to [Section 6. Instruction Glossary](#) for detailed information about individual instructions. [Appendix A. Instruction Reference](#) contains quick-reference material, including an opcode map and postbyte encoding for indexed addressing, transfer/exchange instructions, and loop primitive instructions.

## 5.3 Load and Store Instructions

Load instructions copy memory content into an accumulator or register. Memory content is not changed by the operation. Load instructions (but not LEA\_ instructions) affect condition code bits so no separate test instructions are needed to check the loaded values for negative or 0 conditions.

Store instructions copy the content of a CPU12 register to memory. Register/accumulator content is not changed by the operation. Store instructions automatically update the N and Z condition code bits, which can eliminate the need for a separate test instruction in some programs.

[Table 5-1](#) is a summary of load and store instructions.

**Table 5-1. Load and Store Instructions**

Mnemonic	Function	Operation
<b>Load Instructions</b>		
LDAA	Load A	$(M) \Rightarrow A$
LDAB	Load B	$(M) \Rightarrow B$
LDD	Load D	$(M : M + 1) \Rightarrow (A:B)$
LDS	Load SP	$(M : M + 1) \Rightarrow SP_H:SP_L$
LDX	Load index register X	$(M : M + 1) \Rightarrow X_H:X_L$
LDY	Load index register Y	$(M : M + 1) \Rightarrow Y_H:Y_L$
LEAS	Load effective address into SP	Effective address $\Rightarrow$ SP
LEAX	Load effective address into X	Effective address $\Rightarrow$ X
LEAY	Load effective address into Y	Effective address $\Rightarrow$ Y

Continued on next page

**Table 5-1. Load and Store Instructions (Continued)**

Store Instructions		
STAA	Store A	$(A) \Rightarrow M$
STAB	Store B	$(B) \Rightarrow M$
STD	Store D	$(A) \Rightarrow M, (B) \Rightarrow M + 1$
STS	Store SP	$(SP_H:SP_L) \Rightarrow M : M + 1$
STX	Store X	$(X_H:X_L) \Rightarrow M : M + 1$
STY	Store Y	$(Y_H:Y_L) \Rightarrow M : M + 1$

## 5.4 Transfer and Exchange Instructions

Transfer instructions copy the content of a register or accumulator into another register or accumulator. Source content is not changed by the operation. Transfer register to register (TFR) is a universal transfer instruction, but other mnemonics are accepted for compatibility with the M68HC11. The transfer A to B (TAB) and transfer B to A (TBA) instructions affect the N, Z, and V condition code bits in the same way as M68HC11 instructions. The TFR instruction does not affect the condition code bits.

The sign extend 8-bit operand (SEX) instruction is a special case of the universal transfer instruction that is used to sign extend 8-bit two's complement numbers so that they can be used in 16-bit operations. The 8-bit number is copied from accumulator A, accumulator B, or the condition code register to accumulator D, the X index register, the Y index register, or the stack pointer. All the bits in the upper byte of the 16-bit result are given the value of the most-significant bit (MSB) of the 8-bit number.

Exchange instructions exchange the contents of pairs of registers or accumulators. When the first operand in an EXG instruction is 8-bits and the second operand is 16 bits, a zero-extend operation is performed on the 8-bit register as it is copied into the 16-bit register.

**Section 6. Instruction Glossary** contains information concerning other transfers and exchanges between 8- and 16-bit registers.

**Table 5-2** is a summary of transfer and exchange instructions.

**Table 5-2. Transfer and Exchange Instructions**

Mnemonic	Function	Operation
<b>Transfer Instructions</b>		
TAB	Transfer A to B	(A) ⇒ B
TAP	Transfer A to CCR	(A) ⇒ CCR
TBA	Transfer B to A	(B) ⇒ A
TFR	Transfer register to register	(A, B, CCR, D, X, Y, or SP) ⇒ A, B, CCR, D, X, Y, or SP
TPA	Transfer CCR to A	(CCR) ⇒ A
TSX	Transfer SP to X	(SP) ⇒ X
TSY	Transfer SP to Y	(SP) ⇒ Y
TXS	Transfer X to SP	(X) ⇒ SP
TYS	Transfer Y to SP	(Y) ⇒ SP
<b>Exchange Instructions</b>		
EXG	Exchange register to register	(A, B, CCR, D, X, Y, or SP) ⇔ (A, B, CCR, D, X, Y, or SP)
XGDX	Exchange D with X	(D) ⇔ (X)
XGDY	Exchange D with Y	(D) ⇔ (Y)
<b>Sign Extension Instruction</b>		
SEX	Sign extend 8-Bit operand	Sign-extended (A, B, or CCR) ⇒ D, X, Y, or SP

## 5.5 Move Instructions

Move instructions move (copy) data bytes or words from a source ( $M_1$  or  $M : M + 1_1$ ) to a destination ( $M_2$  or  $M : M + 1_2$ ) in memory. Six combinations of immediate, extended, and indexed addressing are allowed to specify source and destination addresses (IMM  $\Rightarrow$  EXT, IMM  $\Rightarrow$  IDX, EXT  $\Rightarrow$  EXT, EXT  $\Rightarrow$  IDX, IDX  $\Rightarrow$  EXT, IDX  $\Rightarrow$  IDX). Addressing mode combinations with immediate for the destination would not be useful.

**Table 5-3** shows byte and word move instructions.

**Table 5-3. Move Instructions**

Mnemonic	Function	Operation
MOVB	Move byte (8-bit)	$(M_1) \Rightarrow M_2$
MOVW	Move word (16-bit)	$(M : M + 1_1) \Rightarrow M : M + 1_2$

## 5.6 Addition and Subtraction Instructions

Signed and unsigned 8- and 16-bit addition can be performed between registers or between registers and memory. Special instructions support index calculation. Instructions that add the carry bit in the condition code register (CCR) facilitate multiple precision computation.

Signed and unsigned 8- and 16-bit subtraction can be performed between registers or between registers and memory. Special instructions support index calculation. Instructions that subtract the carry bit in the CCR facilitate multiple precision computation. Refer to [Table 5-4](#) for addition and subtraction instructions.

Load effective address (LEAS, LEAX, and LEAY) instructions could also be considered as specialized addition and subtraction instructions. See [5.25 Pointer and Index Calculation Instructions](#) for more information.

**Table 5-4. Addition and Subtraction Instructions**

Mnemonic	Function	Operation
<b>Addition Instructions</b>		
ABA	Add B to A	$(A) + (B) \Rightarrow A$
ABX	Add B to X	$(B) + (X) \Rightarrow X$
ABY	Add B to Y	$(B) + (Y) \Rightarrow Y$
ADCA	Add with carry to A	$(A) + (M) + C \Rightarrow A$
ADCB	Add with carry to B	$(B) + (M) + C \Rightarrow B$
ADDA	Add without carry to A	$(A) + (M) \Rightarrow A$
ADDB	Add without carry to B	$(B) + (M) \Rightarrow B$
ADDD	Add to D	$(A:B) + (M : M + 1) \Rightarrow A : B$
<b>Subtraction Instructions</b>		
SBA	Subtract B from A	$(A) - (B) \Rightarrow A$
SBCA	Subtract with borrow from A	$(A) - (M) - C \Rightarrow A$
SBCB	Subtract with borrow from B	$(B) - (M) - C \Rightarrow B$
SUBA	Subtract memory from A	$(A) - (M) \Rightarrow A$
SUBB	Subtract memory from B	$(B) - (M) \Rightarrow B$
SUBD	Subtract memory from D (A:B)	$(D) - (M : M + 1) \Rightarrow D$

## 5.7 Binary-Coded Decimal Instructions

To add binary-coded decimal (BCD) operands, use addition instructions that set the half-carry bit in the CCR, then adjust the result with the decimal adjust A (DAA) instruction. **Table 5-5** is a summary of instructions that can be used to perform BCD operations.

**Table 5-5. BCD Instructions**

Mnemonic	Function	Operation
ABA	Add B to A	$(A) + (B) \Rightarrow A$
ADCA	Add with carry to A	$(A) + (M) + C \Rightarrow A$
ADCB <sup>(1)</sup>	Add with carry to B	$(B) + (M) + C \Rightarrow B$
ADDA <sup>(1)</sup>	Add memory to A	$(A) + (M) \Rightarrow A$
ADDB	Add memory to B	$(B) + (M) \Rightarrow B$
DAA	Decimal adjust A	$(A)_{10}$

1. These instructions are not normally used for BCD operations because, although they affect H correctly, they do not leave the result in the correct accumulator (A) to be used with the DAA instruction. Thus additional steps would be needed to adjust the result to correct BCD form.

## 5.8 Decrement and Increment Instructions

The decrement and increment instructions are optimized 8- and 16-bit addition and subtraction operations. They are generally used to implement counters. Because they do not affect the carry bit in the CCR, they are particularly well suited for loop counters in multiple-precision computation routines. Refer to [5.20 Loop Primitive Instructions](#) for information concerning automatic counter branches. [Table 5-6](#) is a summary of decrement and increment instructions.

**Table 5-6. Decrement and Increment Instructions**

Mnemonic	Function	Operation
<b>Decrement Instructions</b>		
DEC	Decrement memory	$(M) - \$01 \Rightarrow M$
DECA	Decrement A	$(A) - \$01 \Rightarrow A$
DECB	Decrement B	$(B) - \$01 \Rightarrow B$
DES	Decrement SP	$(SP) - \$0001 \Rightarrow SP$
DEX	Decrement X	$(X) - \$0001 \Rightarrow X$
DEY	Decrement Y	$(Y) - \$0001 \Rightarrow Y$
<b>Increment Instructions</b>		
INC	Increment memory	$(M) + \$01 \Rightarrow M$
INCA	Increment A	$(A) + \$01 \Rightarrow A$
INCB	Increment B	$(B) + \$01 \Rightarrow B$
INS	Increment SP	$(SP) + \$0001 \Rightarrow SP$
INX	Increment X	$(X) + \$0001 \Rightarrow X$
INY	Increment Y	$(Y) + \$0001 \Rightarrow Y$

## 5.9 Compare and Test Instructions

Compare and test instructions perform subtraction between a pair of registers or between a register and memory. The result is not stored, but condition codes are set by the operation. These instructions are generally used to establish conditions for branch instructions. In this architecture, most instructions update condition code bits automatically, so it is often unnecessary to include separate test or compare instructions. [Table 5-7](#) is a summary of compare and test instructions.

**Table 5-7. Compare and Test Instructions**

Mnemonic	Function	Operation
<b>Compare Instructions</b>		
CBA	Compare A to B	$(A) - (B)$
CMPA	Compare A to memory	$(A) - (M)$
CMPB	Compare B to memory	$(B) - (M)$
CPD	Compare D to memory (16-bit)	$(A : B) - (M : M + 1)$
CPS	Compare SP to memory (16-bit)	$(SP) - (M : M + 1)$
CPX	Compare X to memory (16-bit)	$(X) - (M : M + 1)$
CPY	Compare Y to memory (16-bit)	$(Y) - (M : M + 1)$
<b>Test Instructions</b>		
TST	Test memory for zero or minus	$(M) - \$00$
TSTA	Test A for zero or minus	$(A) - \$00$
TSTB	Test B for zero or minus	$(B) - \$00$

## 5.10 Boolean Logic Instructions

The Boolean logic instructions perform a logic operation between an 8-bit accumulator or the CCR and a memory value. AND, OR, and exclusive OR functions are supported. [Table 5-8](#) summarizes logic instructions.

**Table 5-8. Boolean Logic Instructions**

Mnemonic	Function	Operation
ANDA	AND A with memory	$(A) \bullet (M) \Rightarrow A$
ANDB	AND B with memory	$(B) \bullet (M) \Rightarrow B$
ANDCC	AND CCR with memory (clear CCR bits)	$(CCR) \bullet (M) \Rightarrow CCR$
EORA	Exclusive OR A with memory	$(A) \oplus (M) \Rightarrow A$
EORB	Exclusive OR B with memory	$(B) \oplus (M) \Rightarrow B$
ORAA	OR A with memory	$(A) + (M) \Rightarrow A$
ORAB	OR B with memory	$(B) + (M) \Rightarrow B$
ORCC	OR CCR with memory (set CCR bits)	$(CCR) + (M) \Rightarrow CCR$

## 5.11 Clear, Complement, and Negate Instructions

Each of the clear, complement, and negate instructions performs a specific binary operation on a value in an accumulator or in memory. Clear operations clear the value to 0, complement operations replace the value with its one's complement, and negate operations replace the value with its two's complement. **Table 5-9** is a summary of clear, complement, and negate instructions.

**Table 5-9. Clear, Complement, and Negate Instructions**

Mnemonic	Function	Operation
CLC	Clear C bit in CCR	$0 \Rightarrow C$
CLI	Clear I bit in CCR	$0 \Rightarrow I$
CLR	Clear memory	$\$00 \Rightarrow M$
CLRA	Clear A	$\$00 \Rightarrow A$
CLRB	Clear B	$\$00 \Rightarrow B$
CLV	Clear V bit in CCR	$0 \Rightarrow V$
COM	One's complement memory	$\$FF - (M) \Rightarrow M$ or $(\overline{M}) \Rightarrow M$
COMA	One's complement A	$\$FF - (A) \Rightarrow A$ or $(\overline{A}) \Rightarrow A$
COMB	One's complement B	$\$FF - (B) \Rightarrow B$ or $(\overline{B}) \Rightarrow B$
NEG	Two's complement memory	$\$00 - (M) \Rightarrow M$ or $(\overline{M}) + 1 \Rightarrow M$
NEGA	Two's complement A	$\$00 - (A) \Rightarrow A$ or $(\overline{A}) + 1 \Rightarrow A$
NEGB	Two's complement B	$\$00 - (B) \Rightarrow B$ or $(\overline{B}) + 1 \Rightarrow B$

## 5.12 Multiplication and Division Instructions

There are instructions for signed and unsigned 8- and 16-bit multiplication. Eight-bit multiplication operations have a 16-bit product. Sixteen-bit multiplication operations have 32-bit products.

Integer and fractional division instructions have 16-bit dividend, divisor, quotient, and remainder. Extended division instructions use a 32-bit dividend and a 16-bit divisor to produce a 16-bit quotient and a 16-bit remainder.

**Table 5-10** is a summary of multiplication and division instructions.

**Table 5-10. Multiplication and Division Instructions**

Mnemonic	Function	Operation
<b>Multiplication Instructions</b>		
EMUL	16 by 16 multiply (unsigned)	$(D) \times (Y) \Rightarrow Y : D$
EMULS	16 by 16 multiply (signed)	$(D) \times (Y) \Rightarrow Y : D$
MUL	8 by 8 multiply (unsigned)	$(A) \times (B) \Rightarrow A : B$
<b>Division Instructions</b>		
EDIV	32 by 16 divide (unsigned)	$(Y : D) \div (X) \Rightarrow Y$ Remainder $\Rightarrow D$
EDIVS	32 by 16 divide (signed)	$(Y : D) \div (X) \Rightarrow Y$ Remainder $\Rightarrow D$
FDIV	16 by 16 fractional divide	$(D) \div (X) \Rightarrow X$ Remainder $\Rightarrow D$
IDIV	16 by 16 integer divide (unsigned)	$(D) \div (X) \Rightarrow X$ Remainder $\Rightarrow D$
IDIVS	16 by 16 integer divide (signed)	$(D) \div (X) \Rightarrow X$ Remainder $\Rightarrow D$

## 5.13 Bit Test and Manipulation Instructions

The bit test and manipulation operations use a mask value to test or change the value of individual bits in an accumulator or in memory. Bit test A (BITA) and bit test B (BITB) provide a convenient means of testing bits without altering the value of either operand. **Table 5-11** is a summary of bit test and manipulation instructions.

**Table 5-11. Bit Test and Manipulation Instructions**

Mnemonic	Function	Operation
BCLR	Clear bits in memory	$(M) \bullet (\overline{mm}) \Rightarrow M$
BITA	Bit test A	$(A) \bullet (M)$
BITB	Bit test B	$(B) \bullet (M)$
BSET	Set bits in memory	$(M) + (mm) \Rightarrow M$

## 5.14 Shift and Rotate Instructions

There are shifts and rotates for all accumulators and for memory bytes. All pass the shifted-out bit through the C status bit to facilitate multiple-byte operations. Because logical and arithmetic left shifts are identical, there are no separate logical left shift operations. Logic shift left (LSL) mnemonics are assembled as arithmetic shift left memory (ASL) operations. [Table 5-12](#) shows shift and rotate instructions.

**Table 5-12. Shift and Rotate Instructions**

Mnemonic	Function	Operation
<b>Logical Shifts</b>		
LSL LSLA LSLB	Logic shift left memory Logic shift left A Logic shift left B	
LSLD	Logic shift left D	
LSR LSRA LSRB	Logic shift right memory Logic shift right A Logic shift right B	
LSRD	Logic shift right D	
<b>Arithmetic Shifts</b>		
ASL ASLA ASLB	Arithmetic shift left memory Arithmetic shift left A Arithmetic shift left B	
ASLD	Arithmetic shift left D	
ASR ASRA ASRB	Arithmetic shift right memory Arithmetic shift right A Arithmetic shift right B	
<b>Rotates</b>		
ROL ROLA ROLB	Rotate left memory through carry Rotate left A through carry Rotate left B through carry	
ROR RORA RORB	Rotate right memory through carry Rotate right A through carry Rotate right B through carry	

## 5.15 Fuzzy Logic Instructions

The CPU12 instruction set includes instructions that support efficient processing of fuzzy logic operations. The descriptions of fuzzy logic instructions given here are functional overviews. [Table 5-13](#) summarizes the fuzzy logic instructions. Refer to [Section 9. Fuzzy Logic Support](#) for detailed discussion.

### 5.15.1 Fuzzy Logic Membership Instruction

The membership function (MEM) instruction is used during the fuzzification process. During fuzzification, current system input values are compared against stored input membership functions to determine the degree to which each label of each system input is true. This is accomplished by finding the y value for the current input on a trapezoidal membership function for each label of each system input. The MEM instruction performs this calculation for one label of one system input. To perform the complete fuzzification task for a system, several MEM instructions must be executed, usually in a program loop structure.

### 5.15.2 Fuzzy Logic Rule Evaluation Instructions

The MIN-MAX rule evaluation (REV and REVW) instructions perform MIN-MAX rule evaluations that are central elements of a fuzzy logic inference program. Fuzzy input values are processed using a list of rules from the knowledge base to produce a list of fuzzy outputs. The REV instruction treats all rules as equally important. The REVW instruction allows each rule to have a separate weighting factor. The two rule evaluation instructions also differ in the way rules are encoded into the knowledge base. Because they require a number of cycles to execute, rule evaluation instructions can be interrupted. Once the interrupt has been serviced, instruction execution resumes at the point the interrupt occurred.

## 5.15.3 Fuzzy Logic Weighted Average Instruction

The weighted average (WAV) instruction computes a sum-of-products and a sum-of-weights used for defuzzification. To be usable, the fuzzy outputs produced by rule evaluation must be defuzzified to produce a single output value which represents the combined effect of all of the fuzzy outputs. Fuzzy outputs correspond to the labels of a system output and each is defined by a membership function in the knowledge base. The CPU12 typically uses singletons for output membership functions rather than the trapezoidal shapes used for inputs. As with inputs, the x-axis represents the range of possible values for a system output. Singleton membership functions consist of the x-axis position for a label of the system output. Fuzzy outputs correspond to the y-axis height of the corresponding output membership function. The WAV instruction calculates the numerator and denominator sums for a weighted average of the fuzzy outputs. Because WAV requires a number of cycles to execute, it can be interrupted. The WAVR pseudo-instruction causes execution to resume at the point where it was interrupted.

**Table 5-13. Fuzzy Logic Instructions**

Mnemonic	Function	Operation
MEM	Membership function	$\mu(\text{grade}) \Rightarrow M_{(Y)}$ $(X) + 4 \Rightarrow X; (Y) + 1 \Rightarrow Y; A \text{ unchanged}$ <p>if <math>(A) &lt; P1</math> or <math>(A) &gt; P2</math>, then <math>\mu = 0</math>, else  <math>\mu = \text{MIN} [((A) - P1) \times S1, (P2 - (A)) \times S2, \\$FF]</math>                      where:                      A = current crisp input value                      X points to a 4-byte data structure that describes a trapezoidal membership function as base intercept points and slopes (P1, P2, S1, S2)                      Y points at fuzzy input (RAM location)</p>

Continued on next page

**Table 5-13. Fuzzy Logic Instructions (Continued)**

Mnemonic	Function	Operation
REV	MIN-MAX rule evaluation	<p>Find smallest rule input (MIN) Store to rule outputs unless fuzzy output is larger (MAX)</p> <p>Rules are unweighted</p> <p>Each rule input is an 8-bit offset from a base address in Y Each rule output is an 8-bit offset from a base address in Y \$FE separates rule inputs from rule outputs \$FF terminates the rule list</p> <p>REV can be interrupted</p>
REWV	MIN-MAX rule evaluation	<p>Find smallest rule input (MIN) Multiply by a rule weighting factor (optional) Store to rule outputs unless fuzzy output is larger (MAX)</p> <p>Each rule input is the 16-bit address of a fuzzy input Each rule output is the 16-bit address of a fuzzy output Address \$FFFE separates rule inputs from rule outputs \$FFFF terminates the rule list Weights are 8-bit values in a separate table</p> <p>REWV can be interrupted</p>
WAV	Calculates numerator (sum of products) and denominator (sum of weights) for weighted average calculation Results are placed in correct registers for EDIV immediately after WAV	$\sum_{i=1}^B S_i F_i \Rightarrow Y:D$ $\sum_{i=1}^B F_i \Rightarrow X$
WAVR	Resumes execution of interrupted WAV instruction	Recover immediate results from stack rather than initializing them to 0.

## 5.16 Maximum and Minimum Instructions

The maximum (MAX) and minimum (MIN) instructions are used to make comparisons between an accumulator and a memory location. These instructions can be used for linear programming operations, such as simplex-method optimization, or for fuzzification.

MAX and MIN instructions use accumulator A to perform 8-bit comparisons, while EMAX and EMIN instructions use accumulator D to perform 16-bit comparisons. The result (maximum or minimum value) can be stored in the accumulator (EMAXD, EMIND, MAXA, MINA) or the memory address (EMAXM, EMINM, MAXM, MINM).

**Table 5-14** is a summary of minimum and maximum instructions.

**Table 5-14. Minimum and Maximum Instructions**

Mnemonic	Function	Operation
<b>Minimum Instructions</b>		
EMIND	MIN of two unsigned 16-bit values result to accumulator	$\text{MIN}((D), (M : M + 1)) \Rightarrow D$
EMINM	MIN of two unsigned 16-bit values result to memory	$\text{MIN}((D), (M : M + 1)) \Rightarrow M : M+1$
MINA	MIN of two unsigned 8-bit values result to accumulator	$\text{MIN}((A), (M)) \Rightarrow A$
MINM	MIN of two unsigned 8-bit values result to memory	$\text{MIN}((A), (M)) \Rightarrow M$
<b>Maximum Instructions</b>		
EMAXD	MAX of two unsigned 16-bit values result to accumulator	$\text{MAX}((D), (M : M + 1)) \Rightarrow D$
EMAXM	MAX of two unsigned 16-bit values result to memory	$\text{MAX}((D), (M : M + 1)) \Rightarrow M : M + 1$
MAXA	MAX of two unsigned 8-bit values result to accumulator	$\text{MAX}((A), (M)) \Rightarrow A$
MAXM	MAX of two unsigned 8-bit values result to memory	$\text{MAX}((A), (M)) \Rightarrow M$

## 5.17 Multiply and Accumulate Instruction

The multiply and accumulate (EMACS) instruction multiplies two 16-bit operands stored in memory and accumulates the 32-bit result in a third

memory location. EMACS can be used to implement simple digital filters and defuzzification routines that use 16-bit operands. The WAV instruction incorporates an 8- to 16-bit multiply and accumulate operation that obtains a numerator for the weighted average calculation. The EMACS instruction can automate this portion of the averaging operation when 16-bit operands are used. [Table 5-15](#) shows the EMACS instruction.

**Table 5-15. Multiply and Accumulate Instructions**

Mnemonic	Function	Operation
EMACS	Multiply and accumulate (signed) 16 bit by 16 bit $\Rightarrow$ 32 bit	$((M_{(X)}:M_{(X+1)}) \times (M_{(Y)}:M_{(Y+1)}))$ $+ (M \sim M + 3) \Rightarrow M \sim M + 3$

## 5.18 Table Interpolation Instructions

The table interpolation instructions (TBL and ETBL) interpolate values from tables stored in memory. Any function that can be represented as a series of linear equations can be represented by a table of appropriate size. Interpolation can be used for many purposes, including tabular fuzzy logic membership functions. TBL uses 8-bit table entries and returns an 8-bit result; ETBL uses 16-bit table entries and returns a 16-bit result. Use of indexed addressing mode provides great flexibility in structuring tables.

Consider each of the successive values stored in a table to be y-values for the endpoint of a line segment. The value in the B accumulator before instruction execution begins represents the change in x from the beginning of the line segment to the lookup point divided by total change in x from the beginning to the end of the line segment. B is treated as an 8-bit binary fraction with radix point left of the MSB, so each line segment is effectively divided into 256 smaller segments. During instruction execution, the change in y between the beginning and end of the segment (a signed byte for TBL or a signed word for ETBL) is multiplied by the content of the B accumulator to obtain an intermediate delta-y term. The result (stored in the A accumulator by TBL, and in the D accumulator by ETBL) is the y-value of the beginning point plus the signed intermediate delta-y value. [Table 5-16](#) shows the table interpolation instructions.

**Table 5-16. Table Interpolation Instructions**

Mnemonic	Function	Operation
ETBL	16-bit table lookup and interpolate (no indirect addressing modes allowed)	$(M : M + 1) + [(B) \times ((M + 2 : M + 3) - (M : M + 1))] \Rightarrow D$ Initialize B, and index before ETBL. <ea> points to the first table entry (M : M + 1) B is fractional part of lookup value
TBL	8-bit table lookup and interpolate (no indirect addressing modes allowed)	$(M) + [(B) \times ((M + 1) - (M))] \Rightarrow A$ Initialize B, and index before TBL. <ea> points to the first 8-bit table entry (M) B is fractional part of lookup value.

## 5.19 Branch Instructions

Branch instructions cause a sequence to change when specific conditions exist. The CPU12 uses three kinds of branch instructions. These are short branches, long branches, and bit condition branches.

Branch instructions can also be classified by the type of condition that must be satisfied in order for a branch to be taken. Some instructions belong to more than one classification. For example:

- Unary branch instructions always execute.
- Simple branches are taken when a specific bit in the condition code register is in a specific state as a result of a previous operation.
- Unsigned branches are taken when comparison or test of unsigned quantities results in a specific combination of condition code register bits.
- Signed branches are taken when comparison or test of signed quantities results in a specific combination of condition code register bits.

### 5.19.1 Short Branch Instructions

Short branch instructions operate this way: When a specified condition is met, a signed 8-bit offset is added to the value in the program counter. Program execution continues at the new address.

The numeric range of short branch offset values is \$80 (–128) to \$7F (127) from the address of the next memory location after the offset value.

**Table 5-17** is a summary of the short branch instructions.

**Table 5-17. Short Branch Instructions**

Mnemonic	Function	Equation or Operation	
<b>Unary Branches</b>			
BRA	Branch always	$1 = 1$	
BRN	Branch never	$1 = 0$	
<b>Simple Branches</b>			
BCC	Branch if carry clear	$C = 0$	
BCS	Branch if carry set	$C = 1$	
BEQ	Branch if equal	$Z = 1$	
BMI	Branch if minus	$N = 1$	
BNE	Branch if not equal	$Z = 0$	
BPL	Branch if plus	$N = 0$	
BVC	Branch if overflow clear	$V = 0$	
BVS	Branch if overflow set	$V = 1$	
<b>Unsigned Branches</b>			
		<b>Relation</b>	
BHI	Branch if higher	$R > M$	$C + Z = 0$
BHS	Branch if higher or same	$R \geq M$	$C = 0$
BLO	Branch if lower	$R < M$	$C = 1$
BLS	Branch if lower or same	$R \leq M$	$C + Z = 1$
<b>Signed Branches</b>			
BGE	Branch if greater than or equal	$R \geq M$	$N \oplus V = 0$
BGT	Branch if greater than	$R > M$	$Z + (N \oplus V) = 0$
BLE	Branch if less than or equal	$R \leq M$	$Z + (N \oplus V) = 1$
BLT	Branch if less than	$R < M$	$N \oplus V = 1$

### 5.19.2 Long Branch Instructions

Long branch instructions operate this way: When a specified condition is met, a signed 16-bit offset is added to the value in the program counter. Program execution continues at the new address. Long branches are

used when large displacements between decision-making steps are necessary.

The numeric range of long branch offset values is \$8000 (–32,768) to \$7FFF (32,767) from the address of the next memory location after the offset value. This permits branching from any location in the standard 64-Kbyte address map to any other location in the 64-Kbyte map.

**Table 5-18** is a summary of the long branch instructions.

**Table 5-18. Long Branch Instructions**

Mnemonic	Function	Equation or Operation
<b>Unary Branches</b>		
LBRA	Long branch always	$1 = 1$
LBRN	Long branch never	$1 = 0$
<b>Simple Branches</b>		
LBCC	Long branch if carry clear	$C = 0$
LBCS	Long branch if carry set	$C = 1$
LBEQ	Long branch if equal	$Z = 1$
LBMI	Long branch if minus	$N = 1$
LBNE	Long branch if not equal	$Z = 0$
LBPL	Long branch if plus	$N = 0$
LBVC	Long branch if overflow clear	$V = 0$
LBVS	Long branch if overflow set	$V = 1$
<b>Unsigned Branches</b>		
LBHI	Long branch if higher	$C + Z = 0$
LBHS	Long branch if higher or same	$C = 0$
LBLO	Long branch if lower	$Z = 1$
LBLS	Long branch if lower or same	$C + Z = 1$
<b>Signed Branches</b>		
LBGE	Long branch if greater than or equal	$N \oplus V = 0$
LBGT	Long branch if greater than	$Z + (N \oplus V) = 0$
LBLE	Long branch if less than or equal	$Z + (N \oplus V) = 1$
LBLT	Long branch if less than	$N \oplus V = 1$

### 5.19.3 Bit Condition Branch Instructions

The bit condition branches are taken when bits in a memory byte are in a specific state. A mask operand is used to test the location. If all bits in that location that correspond to ones in the mask are set (BRSET) or cleared (BRCLR), the branch is taken.

The numeric range of 8-bit offset values is \$80 (-128) to \$7F (127) from the address of the next memory location after the offset value.

**Table 5-19** is a summary of bit condition branches.

**Table 5-19. Bit Condition Branch Instructions**

Mnemonic	Function	Equation or Operation
BRCLR	Branch if selected bits clear	$(M) \bullet (mm) = 0$
BRSET	Branch if selected bits set	$(\bar{M}) \bullet (mm) = 0$

## 5.20 Loop Primitive Instructions

The loop primitives can also be thought of as counter branches. The instructions test a counter value in a register or accumulator (A, B, D, X, Y, or SP) for zero or non-zero value as a branch condition. There are predecrement, preincrement, and test-only versions of these instructions.

The numeric range of 9-bit offset values is \$100 (-256) to \$0FF (255) from the address of the next memory location after the offset value.

**Table 5-20** is a summary of loop primitive branches.

**Table 5-20. Loop Primitive Instructions**

Mnemonic	Function	Equation or Operation
DBEQ	Decrement counter and branch if = 0 (counter = A, B, D, X, Y, or SP)	$(\text{counter}) - 1 \Rightarrow \text{counter}$ If (counter) = 0, then branch; else continue to next instruction
DBNE	Decrement counter and branch if $\neq$ 0 (counter = A, B, D, X, Y, or SP)	$(\text{counter}) - 1 \Rightarrow \text{counter}$ If (counter) not = 0, then branch; else continue to next instruction
IBEQ	Increment counter and branch if = 0 (counter = A, B, D, X, Y, or SP)	$(\text{counter}) + 1 \Rightarrow \text{counter}$ If (counter) = 0, then branch; else continue to next instruction
IBNE	Increment counter and branch if $\neq$ 0 (counter = A, B, D, X, Y, or SP)	$(\text{counter}) + 1 \Rightarrow \text{counter}$ If (counter) not = 0, then branch; else continue to next instruction
TBEQ	Test counter and branch if = 0 (counter = A, B, D, X, Y, or SP)	If (counter) = 0, then branch; else continue to next instruction
TBNE	Test counter and branch if $\neq$ 0 (counter = A, B, D, X, Y, or SP)	If (counter) not = 0, then branch; else continue to next instruction

## 5.21 Jump and Subroutine Instructions

Jump (JMP) instructions cause immediate changes in sequence. The JMP instruction loads the PC with an address in the 64-Kbyte memory map, and program execution continues at that address. The address can be provided as an absolute 16-bit address or determined by various forms of indexed addressing.

Subroutine instructions optimize the process of transferring control to a code segment that performs a particular task. A short branch (BSR), a jump to subroutine (JSR), or an expanded-memory call (CALL) can be used to initiate subroutines. There is no LBSR instruction, but a PC-relative JSR performs the same function. A return address is stacked, then execution begins at the subroutine address. Subroutines in the normal 64-Kbyte address space are terminated with a return-from-subroutine (RTS) instruction. RTS unstacks the return address so that execution resumes with the instruction after BSR or JSR.

The call subroutine in expanded memory (CALL) instruction is intended for use with expanded memory. CALL stacks the value in the PPAGE register and the return address, then writes a new value to PPAGE to select the memory page where the subroutine resides. The page value is an immediate operand in all addressing modes except indexed indirect modes; in these modes, an operand points to locations in memory where the new page value and subroutine address are stored. The return from call (RTC) instruction is used to terminate subroutines in expanded memory. RTC unstacks the PPAGE value and the return address so that execution resumes with the next instruction after CALL. For software compatibility, CALL and RTC execute correctly on devices that do not have expanded addressing capability. [Table 5-21](#) summarizes the jump and subroutine instructions.

**Table 5-21. Jump and Subroutine Instructions**

Mnemonic	Function	Operation
BSR	Branch to subroutine	$SP - 2 \Rightarrow SP$ $RTN_H : RTN_L \Rightarrow M_{(SP)} : M_{(SP+1)}$ Subroutine address $\Rightarrow PC$
CALL	Call subroutine in expanded memory	$SP - 2 \Rightarrow SP$ $RTN_H : RTN_L \Rightarrow M_{(SP)} : M_{(SP+1)}$ $SP - 1 \Rightarrow SP$ (PPAGE) $\Rightarrow M_{(SP)}$ Page $\Rightarrow PPAGE$ Subroutine address $\Rightarrow PC$
JMP	Jump	Address $\Rightarrow PC$
JSR	Jump to subroutine	$SP - 2 \Rightarrow SP$ $RTN_H : RTN_L \Rightarrow M_{(SP)} : M_{(SP+1)}$ Subroutine address $\Rightarrow PC$
RTC	Return from call	$M_{(SP)} \Rightarrow PPAGE$ $SP + 1 \Rightarrow SP$ $M_{(SP)} : M_{(SP+1)} \Rightarrow PC_H : PC_L$ $SP + 2 \Rightarrow SP$
RTS	Return from subroutine	$M_{(SP)} : M_{(SP+1)} \Rightarrow PC_H : PC_L$ $SP + 2 \Rightarrow SP$

## 5.22 Interrupt Instructions

Interrupt instructions handle transfer of control to a routine that performs a critical task. Software interrupts are a type of exception. [Section 7. Exception Processing](#) covers interrupt exception processing in detail.

The software interrupt (SWI) instruction initiates synchronous exception processing. First, the return PC value is stacked. After CPU12 context is stacked, execution continues at the address pointed to by the SWI vector.

Execution of the SWI instruction causes an interrupt without an interrupt service request. SWI is not inhibited by global mask bits I and X in the CCR, and execution of SWI sets the I mask bit. Once an SWI interrupt begins, maskable interrupts are inhibited until the I bit in the CCR is cleared. This typically occurs when a return from interrupt (RTI) instruction at the end of the SWI service routine restores context.

The CPU12 uses a variation of the software interrupt for unimplemented opcode trapping. There are opcodes in all 256 positions in the page 1 opcode map, but only 54 of the 256 positions on page 2 of the opcode map are used. If the CPU12 attempts to execute one of the unimplemented opcodes on page 2, an opcode trap interrupt occurs. Traps are essentially interrupts that share the \$FFF8:\$FFF9 interrupt vector.

The RTI instruction is used to terminate all exception handlers, including interrupt service routines. RTI first restores the CCR<sub>H</sub> (HCS12X only): CCR, B:A, X, Y, and the return address from the stack. If no other interrupt is pending, normal execution resumes with the instruction following the last instruction that executed prior to interrupt.

**Table 5-22** is a summary of interrupt instructions.

**Table 5-22. Interrupt Instructions**

Mnemonic	Function	Operation
RTI	Return from interrupt	$(M_{(SP)} : M_{(SP+1)}) \Rightarrow CCR_H : CCR; (SP) - \$0000 \Rightarrow SP$ $(M_{(SP)} : M_{(SP+1)}) \Rightarrow B : A; (SP) - \$0002 \Rightarrow SP$ $(M_{(SP)} : M_{(SP+1)}) \Rightarrow X_H : X_L; (SP) - \$0004 \Rightarrow SP$ $(M_{(SP)} : M_{(SP+1)}) \Rightarrow PC_H : PC_L; (SP) - \$0006 \Rightarrow SP$ $(M_{(SP)} : M_{(SP+1)}) \Rightarrow Y_H : Y_L; (SP) - \$0008 \Rightarrow SP$
SWI	Software interrupt	$SP - 2 \Rightarrow SP; RTN_H : RTN_L \Rightarrow M_{(SP)} : M_{(SP+1)}$ $SP - 2 \Rightarrow SP; Y_H : Y_L \Rightarrow M_{(SP)} : M_{(SP+1)}$ $SP - 2 \Rightarrow SP; X_H : X_L \Rightarrow M_{(SP)} : M_{(SP+1)}$ $SP - 2 \Rightarrow SP; B : A \Rightarrow M_{(SP)} : M_{(SP+1)}$ $SP - 2 \Rightarrow SP; CCR_H : CCR \Rightarrow M_{(SP)} : M_{(SP+1)}$
TRAP	Unimplemented opcode interrupt	$SP - 2 \Rightarrow SP; RTN_H : RTN_L \Rightarrow M_{(SP)} : M_{(SP+1)}$ $SP - 2 \Rightarrow SP; Y_H : Y_L \Rightarrow M_{(SP)} : M_{(SP+1)}$ $SP - 2 \Rightarrow SP; X_H : X_L \Rightarrow M_{(SP)} : M_{(SP+1)}$ $SP - 2 \Rightarrow SP; B : A \Rightarrow M_{(SP)} : M_{(SP+1)}$ $SP - 2 \Rightarrow SP; CCR_H : CCR \Rightarrow M_{(SP)} : M_{(SP+1)}$

## 5.23 Index Manipulation Instructions

The index manipulation instructions perform 8- and 16-bit operations on the three index registers and accumulators, other registers, or memory, as shown in [Table 5-23](#).

**Table 5-23. Index Manipulation Instructions**

Mnemonic	Function	Operation
<b>Addition Instructions</b>		
ABX	Add B to X	$(B) + (X) \Rightarrow X$
ABY	Add B to Y	$(B) + (Y) \Rightarrow Y$
<b>Compare Instructions</b>		
CPS	Compare SP to memory	$(SP) - (M : M + 1)$
CPX	Compare X to memory	$(X) - (M : M + 1)$
CPY	Compare Y to memory	$(Y) - (M : M + 1)$
<b>Load Instructions</b>		
LDS	Load SP from memory	$M : M + 1 \Rightarrow SP$
LDX	Load X from memory	$(M : M + 1) \Rightarrow X$
LDY	Load Y from memory	$(M : M + 1) \Rightarrow Y$
LEAS	Load effective address into SP	Effective address $\Rightarrow$ SP
LEAX	Load effective address into X	Effective address $\Rightarrow$ X
LEAY	Load effective address into Y	Effective address $\Rightarrow$ Y
<b>Store Instructions</b>		
STS	Store SP in memory	$(SP) \Rightarrow M : M + 1$
STX	Store X in memory	$(X) \Rightarrow M : M + 1$
STY	Store Y in memory	$(Y) \Rightarrow M : M + 1$
<b>Transfer Instructions</b>		
TFR	Transfer register to register	$(A, B, CCR, D, X, Y, \text{ or } SP) \Rightarrow A, B, CCR, D, X, Y, \text{ or } SP$
TSX	Transfer SP to X	$(SP) \Rightarrow X$
TSY	Transfer SP to Y	$(SP) \Rightarrow Y$
TXS	transfer X to SP	$(X) \Rightarrow SP$
TYS	transfer Y to SP	$(Y) \Rightarrow SP$
<b>Exchange Instructions</b>		
EXG	Exchange register to register	$(A, B, CCR, D, X, Y, \text{ or } SP) \Leftrightarrow (A, B, CCR, D, X, Y, \text{ or } SP)$
XGDY	EXchange D with X	$(D) \Leftrightarrow (X)$
XGDY	EXchange D with Y	$(D) \Leftrightarrow (Y)$

## 5.24 Stacking Instructions

The two types of stacking instructions, are shown in [Table 5-24](#). Stack pointer instructions use specialized forms of mathematical and data transfer instructions to perform stack pointer manipulation. Stack operation instructions save information on and retrieve information from the system stack.

**Table 5-24. Stacking Instructions**

Mnemonic	Function	Operation
<b>Stack Pointer Instructions</b>		
CPS	Compare SP to memory	$(SP) - (M : M + 1)$
DES	Decrement SP	$(SP) - 1 \Rightarrow SP$
INS	Increment SP	$(SP) + 1 \Rightarrow SP$
LDS	Load SP	$(M : M + 1) \Rightarrow SP$
LEAS	Load effective address into SP	Effective address $\Rightarrow SP$
STS	Store SP	$(SP) \Rightarrow M : M + 1$
TSX	Transfer SP to X	$(SP) \Rightarrow X$
TSY	Transfer SP to Y	$(SP) \Rightarrow Y$
TXS	Transfer X to SP	$(X) \Rightarrow SP$
TYS	Transfer Y to SP	$(Y) \Rightarrow SP$
<b>Stack Operation Instructions</b>		
PSHA	Push A	$(SP) - 1 \Rightarrow SP; (A) \Rightarrow M_{(SP)}$
PSHB	Push B	$(SP) - 1 \Rightarrow SP; (B) \Rightarrow M_{(SP)}$
PSHC	Push CCR	$(SP) - 1 \Rightarrow SP; (CCR) \Rightarrow M_{(SP)}$
PSHCW	Push CCR <sub>H</sub> :CCR	$(SP) - 2 \Rightarrow SP; (CCR_H:CCR) \Rightarrow M_{(SP)} : M_{(SP+1)}$
PSHD	Push D	$(SP) - 2 \Rightarrow SP; (A : B) \Rightarrow M_{(SP)} : M_{(SP+1)}$
PSHX	Push X	$(SP) - 2 \Rightarrow SP; (X) \Rightarrow M_{(SP)} : M_{(SP+1)}$
PSHY	Push Y	$(SP) - 2 \Rightarrow SP; (Y) \Rightarrow M_{(SP)} : M_{(SP+1)}$
PULA	Pull A	$(M_{(SP)}) \Rightarrow A; (SP) + 1 \Rightarrow SP$
PULB	Pull B	$(M_{(SP)}) \Rightarrow B; (SP) + 1 \Rightarrow SP$
PULC	Pull CCR	$(M_{(SP)}) \Rightarrow CCR; (SP) + 1 \Rightarrow SP$
PULCW	Pull CCR <sub>H</sub> :CCR	$(M_{(SP)} : M_{(SP+1)}) \Rightarrow CCR_H:CCR; (SP) + 2 \Rightarrow SP$
PULD	Pull D	$(M_{(SP)} : M_{(SP+1)}) \Rightarrow A : B; (SP) + 2 \Rightarrow SP$

**Table 5-24. Stacking Instructions**

PULX	Pull X	$(M_{(SP)} : M_{(SP+1)}) \Rightarrow X; (SP) + 2 \Rightarrow SP$
PULY	Pull Y	$(M_{(SP)} : M_{(SP+1)}) \Rightarrow Y; (SP) + 2 \Rightarrow SP$

## 5.25 Pointer and Index Calculation Instructions

The load effective address instructions allow 5-, 8-, or 16-bit constants or the contents of 8-bit accumulators A and B or 16-bit accumulator D to be added to the contents of the X and Y index registers, or to the SP.

**Table 5-25** is a summary of pointer and index instructions.

**Table 5-25. Pointer and Index Calculation Instructions**

Mnemonic	Function	Operation
LEAS	Load result of indexed addressing mode effective address calculation into stack pointer	$r \pm \text{constant} \Rightarrow SP$ or $(r) + (\text{accumulator}) \Rightarrow SP$ $r = X, Y, SP, \text{ or } PC$
LEAX	Load result of indexed addressing mode effective address calculation into x index register	$r \pm \text{constant} \Rightarrow X$ or $(r) + (\text{accumulator}) \Rightarrow X$ $r = X, Y, SP, \text{ or } PC$
LEAY	Load result of indexed addressing mode effective address calculation into y index register	$r \pm \text{constant} \Rightarrow Y$ or $(r) + (\text{accumulator}) \Rightarrow Y$ $r = X, Y, SP, \text{ or } PC$

## 5.26 Condition Code Instructions

Condition code instructions are special forms of mathematical and data transfer instructions that can be used to change the condition code register. [Table 5-26](#) shows instructions that can be used to manipulate the CCR.

**Table 5-26. Condition Code Instructions**

Mnemonic	Function	Operation
ANDCC	Logical AND CCR with memory	$(CCR) \bullet (M) \Rightarrow CCR$
CLC	Clear C bit	$0 \Rightarrow C$
CLI	Clear I bit	$0 \Rightarrow I$
CLV	Clear V bit	$0 \Rightarrow V$
ORCC	Logical OR CCR with memory	$(CCR) + (M) \Rightarrow CCR$
PSHC	Push CCR onto stack	$(SP) - 1 \Rightarrow SP; CCR \Rightarrow M_{(SP)}$
PSHCW	Push CCR <sub>H</sub> :CCR onto stack	$(SP) - 2 \Rightarrow SP; (CCR_H:CCR) \Rightarrow M_{(SP)}:M_{(SP+1)}$
PULC	Pull CCR from stack	$M_{(SP)} \Rightarrow CCR; (SP) + 1 \Rightarrow SP$
PULCW	Pull CCR <sub>H</sub> :CCR from stack	$M_{(SP)}:M_{(SP+1)} \Rightarrow CCR_H:CCR; (SP) + 2 \Rightarrow SP$
SEC	Set C bit	$1 \Rightarrow C$
SEI	Set I bit	$1 \Rightarrow I$
SEV	Set V bit	$1 \Rightarrow V$
TAP	Transfer A to CCR	$(A) \Rightarrow CCR$
TPA	Transfer CCR to A	$(CCR) \Rightarrow A$

## 5.27 Stop and Wait Instructions

As shown in [Table 5-27](#), two instructions put the CPU12 in an inactive state that reduces power consumption.

The stop instruction (STOP) stacks a return address and the contents of CPU12 registers and accumulators, then halts all system clocks.

The wait instruction (WAI) stacks a return address and the contents of CPU12 registers and accumulators, then waits for an interrupt service request; however, system clock signals continue to run.

Both STOP and WAI require that either an interrupt or a reset exception occur before normal execution of instructions resumes. Although both instructions require the same number of clock cycles to resume normal program execution after an interrupt service request is made, restarting after a STOP requires extra time for the oscillator to reach operating speed.

**Table 5-27. Stop and Wait Instructions**

Mnemonic	Function	Operation
STOP	Stop	$SP - 2 \Rightarrow SP; RTN_H : RTN_L \Rightarrow M_{(SP)} : M_{(SP+1)}$ $SP - 2 \Rightarrow SP; Y_H : Y_L \Rightarrow M_{(SP)} : M_{(SP+1)}$ $SP - 2 \Rightarrow SP; X_H : X_L \Rightarrow M_{(SP)} : M_{(SP+1)}$ $SP - 2 \Rightarrow SP; B : A \Rightarrow M_{(SP)} : M_{(SP+1)}$ $SP - 2 \Rightarrow SP; CCR_H : CCR \Rightarrow M_{(SP)} M_{(SP+1)}$ Stop CPU clocks
WAI	Wait for interrupt	$SP - 2 \Rightarrow SP; RTN_H : RTN_L \Rightarrow M_{(SP)} : M_{(SP+1)}$ $SP - 2 \Rightarrow SP; Y_H : Y_L \Rightarrow M_{(SP)} : M_{(SP+1)}$ $SP - 2 \Rightarrow SP; X_H : X_L \Rightarrow M_{(SP)} : M_{(SP+1)}$ $SP - 2 \Rightarrow SP; B : A \Rightarrow M_{(SP)} : M_{(SP+1)}$ $SP - 2 \Rightarrow SP; CCR_H : CCR \Rightarrow M_{(SP)} : M_{(SP+1)}$

## 5.28 Background Mode and Null Operations

Background debug mode (BDM) is a special CPU12 operating mode that is used for system development and debugging. Executing enter background debug mode (BGND) when BDM is enabled puts the CPU12 in this mode. For complete information, refer to [Section 8. Instruction Queue](#).

Null operations are often used to replace other instructions during software debugging. Replacing conditional branch instructions with branch never (BRN), for instance, permits testing a decision-making routine by disabling the conditional branch without disturbing the offset value.

Null operations can also be used in software delay programs to consume execution time without disturbing the contents of other CPU12 registers or memory.

[Table 5-28](#) shows the BGND and null operation (NOP) instructions.

**Table 5-28. Background Mode and Null Operation Instructions**

Mnemonic	Function	Operation
BGND	Enter background debug mode	If BDM enabled, enter BDM; else resume normal processing
BRN	Branch never	Does not branch
LBRN	Long branch never	Does not branch
NOP	Null operation	—

## Section 6. Instruction Glossary

### 6.1 Introduction

This section is a comprehensive reference to the S12X CPU instruction set. New instructions are denoted with

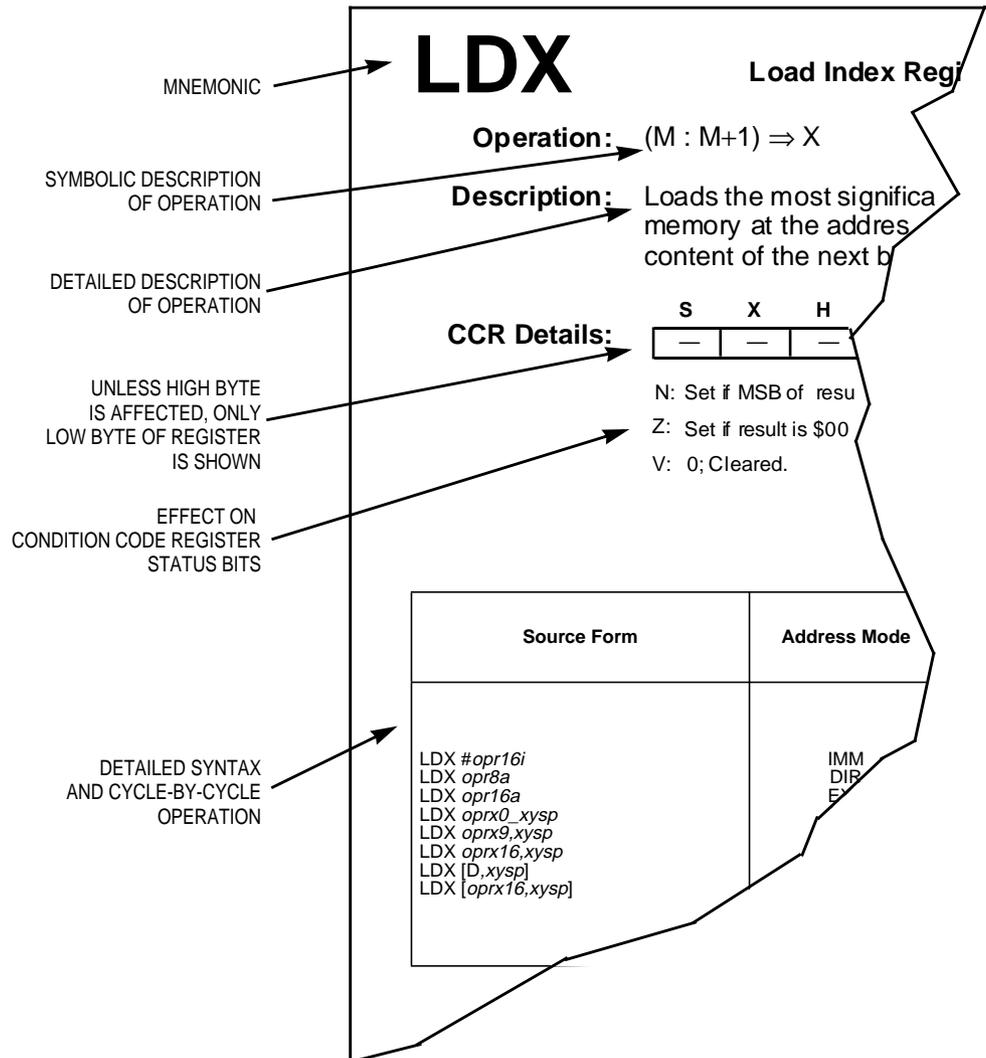

**reverse printing**

S12 CPU information is included for a reference point of view.

**NOTE:** *The glossary contains condition code register (CCR) details for each assembler mnemonic. Unless the high byte is affected, only the low byte of the condition code register is shown.*

### 6.2 Glossary Information

The glossary contains an entry for each assembler mnemonic, in alphabetic order. [Figure 6-1](#) is a representation of a glossary page.

**Figure 6-1. Example Glossary Page**

Each entry contains symbolic and textual descriptions of operation, information concerning the effect of operation on status bits in the condition code register, and a table that describes assembler syntax, address mode variations, and cycle-by-cycle execution of the instruction.

## 6.3 Condition Code Changes

The following special characters are used to describe the effects of instruction execution on the status bits in the condition code register.

- — Status bit not affected by operation
- 0 — Status bit cleared by operation
- 1 — Status bit set by operation
- Δ — Status bit affected by operation
- ⇓ — Status bit may be cleared or remain set, but is not set by operation.
- ⇑ — Status bit may be set or remain cleared, but is not cleared by operation.
- ? — Status bit may be changed by operation, but the final state is not defined.
- ! — Status bit used for a special purpose

## 6.4 Object Code Notation

The digits 0 to 9 and the uppercase letters A to F are used to express hexadecimal values. Pairs of lowercase letters represent the 8-bit values as described here.

- dd — 8-bit direct address \$0000 to \$00FF; high byte assumed to be \$00
- ee — High-order byte of a 16-bit constant offset for indexed addressing
- eb — Exchange/transfer post-byte
- ff — Low-order eight bits of a 9-bit signed constant offset for indexed addressing, or low-order byte of a 16-bit constant offset for indexed addressing
- hh — High-order byte of a 16-bit extended address
- ii — 8-bit immediate data value
- jj — High-order byte of a 16-bit immediate data value
- kk — Low-order byte of a 16-bit immediate data value
- lb — Loop primitive (DBNE) post-byte
- ll — Low-order byte of a 16-bit extended address
- mm — 8-bit immediate mask value for bit manipulation instructions; set bits indicate bits to be affected
- pg — Program overlay page (bank) number used in CALL instruction
- qq — High-order byte of a 16-bit relative offset for long branches
- tn — Trap number \$30–\$39 or \$40–\$FF
- rr — Signed relative offset \$80 (–128) to \$7F (+127) offset relative to the byte following the relative offset byte, or low-order byte of a 16-bit relative offset for long branches
- xb — Indexed addressing post-byte

## 6.5 Source Forms

The glossary pages provide only essential information about assembler source forms. Assemblers generally support a number of assembler directives, allow definition of program labels, and have special conventions for comments. For complete information about writing source files for a particular assembler, refer to the documentation provided by the assembler vendor.

Assemblers are typically flexible about the use of spaces and tabs. Often, any number of spaces or tabs can be used where a single space is shown on the glossary pages. Spaces and tabs are also normally allowed before and after commas. When program labels are used, there must also be at least one tab or space before all instruction mnemonics. This required space is not apparent in the source forms.

Everything in the source forms columns, *except expressions in italic characters*, is literal information which must appear in the assembly source file exactly as shown. The initial 3- to 5-letter mnemonic is always a literal expression. All commas, pound signs (#), parentheses, square brackets ( [ or ] ), plus signs (+), minus signs (–), and the register designation D (as in [D,... ]), are literal characters.

Groups of italic characters in the columns represent variable information to be supplied by the programmer. These groups can include any alphanumeric character or the underscore character, but cannot include a space or comma. For example, the groups *xysp* and *oprX0\_xysp* are both valid, but the two groups *oprX0 xysp* are not valid because there is a space between them. Permitted syntax is described here.

The definition of a legal label or expression varies from assembler to assembler. Assemblers also vary in the way CPU12 registers are specified. Refer to assembler documentation for detailed information. Recommended register designators are a, A, b, B, ccr, CCR, d, D, x, X, y, Y, sp, SP, pc, and PC.

*abc* — Any one legal register designator for accumulators A or B or the CCR

*abcdxys* — Any one legal register designator for accumulators A or B, the CCR, the double accumulator D, index registers X or Y, or the SP. Some assemblers may accept t2, T2, t3, or T3 codes in certain cases of transfer and exchange

instructions, but these forms are intended for Motorola use only.

- abd* — Any one legal register designator for accumulators A or B or the double accumulator D
- abdxys* — Any one legal register designator for accumulators A or B, the double accumulator D, index register X or Y, or the SP
- dxys* — Any one legal register designation for the double accumulator D, index registers X or Y, or the SP
- msk8* — Any label or expression that evaluates to an 8-bit value. Some assemblers require a # symbol before this value.
- opr8i* — Any label or expression that evaluates to an 8-bit immediate value
- opr16i* — Any label or expression that evaluates to a 16-bit immediate value
- opr8a* — Any label or expression that evaluates to an 8-bit value. The instruction treats this 8-bit value as the low-order 8 bits of an address in the direct page of the 64-Kbyte address space (\$00xx).
- opr16a* — Any label or expression that evaluates to a 16-bit value. The instruction treats this value as an address in the 64-Kbyte address space.
- opr0\_xysp* — This word breaks down into one of the following alternative forms that assemble to an 8-bit indexed addressing postbyte code. These forms generate the same object code except for the value of the postbyte code, which is designated as *xb* in the object code columns of the glossary pages. As with the source forms, treat all commas, plus signs, and minus signs as literal syntax elements. The italicized words used in these forms are included in this key.
- opr5,xysp*
  - opr3,-xys*
  - opr3,+xys*
  - opr3,xys-*
  - opr3,xys+*
  - abd,xysp*

- opr3* — Any label or expression that evaluates to a value in the range +1 to +8
- opr5* — Any label or expression that evaluates to a 5-bit value in the range –16 to +15
- opr9* — Any label or expression that evaluates to a 9-bit value in the range –256 to +255
- opr16* — Any label or expression that evaluates to a 16-bit value. Since the CPU12 has a 16-bit address bus, this can be either a signed or an unsigned value.
- page* — Any label or expression that evaluates to an 8-bit value. The CPU12 recognizes up to an 8-bit page value for memory expansion but not all MCUs that include the CPU12 implement all of these bits. It is the programmer's responsibility to limit the page value to legal values for the intended MCU system. Some assemblers require a # symbol before this value.
- rel8* — Any label or expression that refers to an address that is within –128 to +127 locations from the next address after the last byte of object code for the current instruction. The assembler will calculate the 8-bit signed offset and include it in the object code for this instruction.
- rel9* — Any label or expression that refers to an address that is within –256 to +255 locations from the next address after the last byte of object code for the current instruction. The assembler will calculate the 9-bit signed offset and include it in the object code for this instruction. The sign bit for this 9-bit value is encoded by the assembler as a bit in the looping postbyte (lb) of one of the loop control instructions DBEQ, DBNE, IBEQ, IBNE, TBEQ, or TBNE. The remaining eight bits of the offset are included as an extra byte of object code.
- rel16* — Any label or expression that refers to an address anywhere in the 64-Kbyte address space. The assembler will calculate the 16-bit signed offset between this address and the next address after the last byte of object code for this instruction and include it in the object code for this instruction.

- trapnum* — Any label or expression that evaluates to an 8-bit number in the range \$30–\$39 or \$40–\$FF. Used for TRAP instruction.
- xys* — Any one legal register designation for index registers X or Y or the SP
- xysp* — Any one legal register designation for index registers X or Y, the SP, or the PC. The reference point for PC-relative instructions is the next address after the last byte of object code for the current instruction.

### 6.6 Cycle-by-Cycle Execution

This information is found in the tables at the bottom of each instruction glossary page. Entries show how many bytes of information are accessed from different areas of memory during the course of instruction execution. With this information and knowledge of the type and speed of memory in the system, a user can determine the execution time for any instruction in any system.

A single letter code in the column represents a single CPU12 cycle. Uppercase letters indicate 16-bit access cycles. There are cycle codes for each addressing mode variation of each instruction. Simply count code letters to determine the execution time of an instruction in a best-case system. An example of a best-case system is a single-chip 16-bit system with no 16-bit off-boundary data accesses to any locations other than on-chip RAM.

Many conditions can cause one or more instruction cycles to be stretched, but the CPU12 is not aware of the stretch delays because the clock to the CPU12 is temporarily stopped during these delays.

The following paragraphs explain the cycle code letters used and note conditions that can cause each type of cycle to be stretched.

- f* — Free cycle. This indicates a cycle where the CPU12 does not require use of the system buses. An *f* cycle is always one cycle of the system bus clock. These cycles can be used by a queue controller or the background debug system to perform single cycle accesses without disturbing the CPU12.

- g — Read 8-bit PPAGE register. These cycles are used only with the CALL instruction to read the current value of the PPAGE register and are not visible on the external bus. Since the PPAGE register is an internal 8-bit register, these cycles are never stretched.
  - l — Read indirect pointer. Indexed indirect instructions use this 16-bit pointer from memory to address the operand for the instruction. These are always 16-bit reads but they can be either aligned or misaligned. These cycles are extended to two bus cycles if the MCU is operating with an 8-bit external data bus and the corresponding data is stored in external memory. There can be additional stretching when the address space is assigned to a chip-select circuit programmed for slow memory. These cycles are also stretched if they correspond to misaligned access to a memory that is not designed for single-cycle misaligned access.
  - i — Read indirect PPAGE value. These cycles are only used with indexed indirect versions of the CALL instruction, where the 8-bit value for the memory expansion page register of the CALL destination is fetched from an indirect memory location. These cycles are stretched only when controlled by a chip-select circuit that is programmed for slow memory.
  - n — Write 8-bit PPAGE register. These cycles are used only with the CALL and RTC instructions to write the destination value of the PPAGE register and are not visible on the external bus. Since the PPAGE register is an internal 8-bit register, these cycles are never stretched.
- NA — Not available

- O — Optional cycle. Program information is always fetched as aligned 16-bit words. When an instruction consists of an odd number of bytes, and the first byte is misaligned, an O cycle is used to make an additional program word access (P) cycle that maintains queue order. In all other cases, the O cycle appears as a free (f) cycle. The \$18 prebyte for page two opcodes is treated as a special 1-byte instruction. If the prebyte is misaligned, the O cycle is used as a program word access for the prebyte; if the prebyte is aligned, the O cycle appears as a free cycle. If the remainder of the instruction consists of an odd number of bytes, another O cycle is required some time before the instruction is completed. If the O cycle for the prebyte is treated as a P cycle, any subsequent O cycle in the same instruction is treated as an f cycle; if the O cycle for the prebyte is treated as an f cycle, any subsequent O cycle in the same instruction is treated as a P cycle. Optional cycles used for program word accesses can be extended to two bus cycles if the MCU is operating with an 8-bit external data bus and the program is stored in external memory. There can be additional stretching when the address space is assigned to a chip-select circuit programmed for slow memory. Optional cycles used as free cycles are never stretched.
- P — Program word access. Program information is fetched as aligned 16-bit words. These cycles are extended to two bus cycles if the MCU is operating with an 8-bit external data bus and the program is stored externally. There can be additional stretching when the address space is assigned to a chip-select circuit programmed for slow memory.
- r — 8-bit data read. These cycles are stretched only when controlled by a chip-select circuit programmed for slow memory.

- R — 16-bit data read. These cycles are extended to two bus cycles if the MCU is operating with an 8-bit external data bus and the corresponding data is stored in external memory. There can be additional stretching when the address space is assigned to a chip-select circuit programmed for slow memory. These cycles are also stretched if they correspond to misaligned accesses to memory that is not designed for single-cycle misaligned access.
- s — Stack 8-bit data. These cycles are stretched only when controlled by a chip-select circuit programmed for slow memory.
- S — Stack 16-bit data. These cycles are extended to two bus cycles if the MCU is operating with an 8-bit external data bus and the SP is pointing to external memory. There can be additional stretching if the address space is assigned to a chip-select circuit programmed for slow memory. These cycles are also stretched if they correspond to misaligned accesses to a memory that is not designed for single cycle misaligned access. The internal RAM is designed to allow single cycle misaligned word access.
- w — 8-bit data write. These cycles are stretched only when controlled by a chip-select circuit programmed for slow memory.
- W — 16-bit data write. These cycles are extended to two bus cycles if the MCU is operating with an 8-bit external data bus and the corresponding data is stored in external memory. There can be additional stretching when the address space is assigned to a chip-select circuit programmed for slow memory. These cycles are also stretched if they correspond to misaligned access to a memory that is not designed for single-cycle misaligned access.
- u — Unstack 8-bit data. These cycles are stretched only when controlled by a chip-select circuit programmed for slow memory.

- U — Unstack 16-bit data. These cycles are extended to two bus cycles if the MCU is operating with an 8-bit external data bus and the SP is pointing to external memory. There can be additional stretching when the address space is assigned to a chip-select circuit programmed for slow memory. These cycles are also stretched if they correspond to misaligned accesses to a memory that is not designed for single-cycle misaligned access. The internal RAM is designed to allow single-cycle misaligned word access.
- V — Vector fetch. Vectors are always aligned 16-bit words. These cycles are extended to two bus cycles if the MCU is operating with an 8-bit external data bus and the program is stored in external memory. There can be additional stretching when the address space is assigned to a chip-select circuit programmed for slow memory.
- t — 8-bit conditional read. These cycles are either data read cycles or unused cycles, depending on the data and flow of the REVW instruction. These cycles are stretched only when controlled by a chip-select circuit programmed for slow memory.
- T — 16-bit conditional read. These cycles are either data read cycles or free cycles, depending on the data and flow of the REV or REVW instruction. These cycles are extended to two bus cycles if the MCU is operating with an 8-bit external data bus and the corresponding data is stored in external memory. There can be additional stretching when the address space is assigned to a chip-select circuit programmed for slow memory. These cycles are also stretched if they correspond to misaligned accesses to a memory that is not designed for single-cycle misaligned access.
- x — 8-bit conditional write. These cycles are either data write cycles or free cycles, depending on the data and flow of the REV or REVW instruction. These cycles are only stretched when controlled by a chip-select circuit programmed for slow memory.

### Special Notation for Branch Taken/Not Taken Cases

- PPP/P — Short branches require three cycles if taken, one cycle if not taken. Since the instruction consists of a single word containing both an opcode and an 8-bit offset, the not-taken case is simple — the queue advances, another program word fetch is made, and execution continues with the next instruction. The taken case requires that the queue be refilled so that execution can continue at a new address. First, the effective address of the destination is determined, then the CPU12 performs three program word fetches from that address.
- OPPP/OPO — Long branches require four cycles if taken, three cycles if not taken. Optional cycles are required because all long branches are page two opcodes, and thus include the \$18 prebyte. The CPU12 treats the prebyte as a special 1-byte instruction. If the prebyte is misaligned, the optional cycle is used to perform a program word access; if the prebyte is aligned, the optional cycle is used to perform a free cycle. As a result, both the taken and not-taken cases use one optional cycle for the prebyte. In the not-taken case, the queue must advance so that execution can continue with the next instruction, and another optional cycle is required to maintain the queue. The taken case requires that the queue be refilled so that execution can continue at a new address. First, the effective address of the destination is determined, then the CPU12 performs three program word fetches from that address.

## 6.7 Glossary

This subsection contains an entry for each assembler mnemonic, in alphabetic order.

# ABA

Add Accumulator B to Accumulator A

# ABA

**Operation:**  $(A) + (B) \Rightarrow A$

**Description:** Adds the content of accumulator B to the content of accumulator A and places the result in A. The content of B is not changed. This instruction affects the H status bit so it is suitable for use in BCD arithmetic operations. See [DAA](#) instruction for additional information.

**CCR Details:**

S	X	H	I	N	Z	V	C
-	-	Δ	-	Δ	Δ	Δ	Δ

H:  $A3 \cdot B3 + B3 \cdot \overline{R3} + \overline{R3} \cdot A3$

Set if there was a carry from bit 3; cleared otherwise

N: Set if MSB of result is set; cleared otherwise

Z: Set if result is \$00; cleared otherwise

V:  $A7 \cdot B7 \cdot \overline{R7} + \overline{A7} \cdot \overline{B7} \cdot R7$

# ABX

## Add Accumulator B to Index Register X

# ABX

**Operation:**  $(B) + (X) \Rightarrow X$

**Description:** Adds the 8-bit unsigned content of accumulator B to the content of index register X considering the possible carry out of the low-order byte of X; places the result in X. The content of B is not changed.

This mnemonic is implemented by the LEAX B,X instruction. The LEAX instruction allows A, B, D, or a constant to be added to X. For compatibility with the M68HC11, the mnemonic ABX is translated into the LEAX B,X instruction by the assembler.

**CCR Details:**

# ABY

Add Accumulator B to Index Register Y

# ABY

**Operation:** (B) + (Y) ⇒ Y

**Description:** Adds the 8-bit unsigned content of accumulator B to the content of index register Y considering the possible carry out of the low-order byte of Y; places the result in Y. The content of B is not changed.

This mnemonic is implemented by the LEAY B,Y instruction. The LEAY instruction allows A, B, D, or a constant to be added to Y. For compatibility with the M68HC11, the mnemonic ABY is translated into the LEAY B,Y instruction by the assembler.

# ANDCC

Logical AND CCR with Mask

# ANDCC

**Operation:** (CCR) • (Mask) ⇒ CCR

**Description:** Performs bitwise logical AND between the content of a mask operand and the content of the CCR. The result is placed in the CCR. After the operation is performed, each bit of the CCR is the result of a logical AND with the corresponding bits of the mask. To clear CCR bits, clear the corresponding mask bits. CCR bits that correspond to ones in the mask are not changed by the ANDCC operation.

If the I mask bit is cleared, there is a 1-cycle delay before the system allows interrupt requests. This prevents interrupts from occurring between instructions in the sequences CLI, WAI and CLI, SEI (CLI is equivalent to ANDCC #\$EF).

**CCR Details:**

S	X	H	I	N	Z	V	C
⇓	⇓	⇓	⇓	⇓	⇓	⇓	⇓

Condition code bits are cleared if the corresponding bit was 0 before the operation or if the corresponding bit in the mask is 0.

# BGE

## Branch if Greater than or Equal to Zero

# BGE

**Operation:** If  $N \oplus V = 0$ , then  $(PC) + \$0002 + Rel \Rightarrow PC$

For signed two's complement values  
if (Accumulator)  $\geq$  (Memory), then branch

**Description:** BGE can be used to branch after comparing or subtracting signed two's complement values. After CMPA, CMPB, CPD, CPS, CPX, CPY, SBCA, SBCB, SUBA, SUBB, or SUBD, the branch occurs if the CPU12 register value is greater than or equal to the value in M. After CBA or SBA, the branch occurs if the value in B is greater than or equal to the value in A.

See [3.9 Relative Addressing Mode](#) for details of branch execution.

# BGND

## Enter Background Debug Mode

# BGND

**Description:** BGND operates like a software interrupt, except that no registers are stacked. First, the current PC value is stored in internal CPU12 register TMP2. Next, the BDM ROM and background register block become active. The BDM ROM contains a substitute vector, mapped to the address of the software interrupt vector, which points to routines in the BDM ROM that control background operation. The substitute vector is fetched, and execution continues from the address that it points to. Finally, the CPU12 checks the location that TMP2 points to. If the value stored in that location is \$00 (the BGND opcode), TMP2 is incremented, so that the instruction that follows the BGND instruction is the first instruction executed when normal program execution resumes.

For all other types of BDM entry, the CPU12 performs the same sequence of operations as for a BGND instruction, but the value stored in TMP2 already points to the instruction that would have executed next had BDM not become active. If active BDM is triggered just as a BGND instruction is about to execute, the BDM firmware does increment TMP2, but the change does not affect resumption of normal execution.

While BDM is active, the CPU12 executes debugging commands received via a special single-wire serial interface. BDM is terminated by the execution of specific debugging commands. Upon exit from BDM, the background/boot ROM and registers are disabled, the instruction queue is refilled starting with the return address pointed to by TMP2, and normal processing resumes.

BDM is normally disabled to avoid accidental entry. While BDM is disabled, BGND executes as described, but the firmware causes execution to return to the user program. Refer to [Section 4. Instruction Queue](#) for more information concerning BDM.

# BGT

## Branch if Greater than Zero

# BGT

**Operation:** If  $Z + (N \oplus V) = 0$ , then  $(PC) + \$0002 + Rel \Rightarrow PC$

For signed two's complement values  
if (Accumulator) > (Memory), then branch

**Description:** BGT can be used to branch after comparing or subtracting signed two's complement values. After CMPA, CMPB, CPD, CPS, CPX, CPY, SBCA, SBCB, SUBA, SUBB, or SUBD, the branch occurs if the CPU12 register value is greater than the value in M. After CBA or SBA, the branch occurs if the value in B is greater than the value in A.

See [3.9 Relative Addressing Mode](#) for details of branch execution.

# BLS

Branch if Lower or Same

# BLS

**Operation:** If  $C + Z = 1$ , then  $(PC) + \$0002 + Rel \Rightarrow PC$

For unsigned values, if  $(Accumulator) \leq (Memory)$ , then branch

**Description:** If BLS is executed immediately after execution of CBA, CMPA, CMPB, CMPD, CPX, CPY, SBA, SUBA, SUBB, or SUBD, a branch occurs if and only if the unsigned binary number in the accumulator is less than or equal to the unsigned binary number in memory. Generally not useful after INC/DEC, LD/ST, and TST/CLR/COM because these instructions do not affect the C status bit.

See [3.9 Relative Addressing Mode](#) for details of branch execution.

# BRA

## Branch Always

# BRA

**Operation:**  $(PC) + \$0002 + Rel \Rightarrow PC$

**Description:** Unconditional branch to an address calculated as shown in the expression. Rel is a relative offset stored as a two's complement number in the second byte of the branch instruction.

Execution time is longer when a conditional branch is taken than when it is not, because the instruction queue must be refilled before execution resumes at the new address. Since the BRA branch condition is always satisfied, the branch is always taken, and the instruction queue must always be refilled.

See [3.9 Relative Addressing Mode](#) for details of branch execution.

# BRCLR

Branch if Bits Cleared

# BRCLR

**Operation:** If (M) • (Mask) = 0, then branch

**Description:** Performs a bitwise logical AND of memory location M and the mask supplied with the instruction, then branches if and only if all bits with a value of 1 in the mask byte correspond to bits with a value of 0 in the tested byte. Mask operands can be located at PC + 1, PC + 2, or PC + 4, depending on addressing mode. The branch offset is referenced to the next address after the relative offset (rr) which is the last byte of the instruction object code.

See [3.9 Relative Addressing Mode](#) for details of branch execution.

**CCR Details:**

1. Indirect forms of indexed addressing cannot be used with this instruction.

# BRN

Branch Never

# BRN

**Operation:** (PC) + \$0002 ⇒ PC

**Description:** Never branches. BRN is effectively a 2-byte NOP that requires one cycle to execute. BRN is included in the instruction set to provide a complement to the BRA instruction. The instruction is useful during program debug, to negate the effect of another branch instruction without disturbing the offset byte. A complement for BRA is also useful in compiler implementations.

Execution time is longer when a conditional branch is taken than when it is not, because the instruction queue must be refilled before execution resumes at the new address. Since the BRN branch condition is never satisfied, the branch is never taken, and only a single program fetch is needed to update the instruction queue.

See [3.9 Relative Addressing Mode](#) for details of branch execution.

# BSR

## Branch to Subroutine

# BSR

**Operation:**  $(SP) - \$0002 \Rightarrow SP$   
 $RTN_H : RTN_L \Rightarrow M_{(SP)} : M_{(SP+1)}$   
 $(PC) + Rel \Rightarrow PC$

**Description:** Sets up conditions to return to normal program flow, then transfers control to a subroutine. Uses the address of the instruction after the BSR as a return address.

Decrements the SP by two, to allow the two bytes of the return address to be stacked.

Stacks the return address (the SP points to the high-order byte of the return address).

Branches to a location determined by the branch offset.

Subroutines are normally terminated with an RTS instruction, which restores the return address from the stack.

1. Indirect forms of indexed addressing cannot be used with this instruction.

# BVC

## Branch if Overflow Cleared

# BVC

**Operation:** If  $V = 0$ , then  $(PC) + \$0002 + Rel \Rightarrow PC$

Simple branch

**Description:** Tests the V status bit and branches if  $V = 0$ .

BVC causes a branch when a previous operation on two's complement binary values does not cause an overflow. That is, when BVC follows a two's complement operation, a branch occurs when the result of the operation is valid.

See [3.9 Relative Addressing Mode](#) for details of branch execution.

# BVS

## Branch if Overflow Set

# BVS

**Operation:** If  $V = 1$ , then  $(PC) + \$0002 + Rel \Rightarrow PC$

Simple branch

**Description:** Tests the V status bit and branches if  $V = 1$ .

BVS causes a branch when a previous operation on two's complement binary values causes an overflow. That is, when BVS follows a two's complement operation, a branch occurs when the result of the operation is invalid.

See [3.9 Relative Addressing Mode](#) for details of branch execution.

# CALL

## Call Subroutine in Expanded Memory

# CALL

**Operation:** (SP) – \$0002 ⇒ SP; RTN<sub>H</sub> : RTN<sub>L</sub> ⇒ M<sub>(SP)</sub> : M<sub>(SP+1)</sub>  
 (SP) – \$0001 ⇒ SP; (PPAGE) ⇒ M<sub>(SP)</sub>  
 page ⇒ PPAGE; Subroutine Address ⇒ PC

**Description:** Sets up conditions to return to normal program flow, then transfers control to a subroutine in expanded memory. Uses the address of the instruction following the CALL as a return address. For code compatibility, CALL also executes correctly in devices that do not have expanded memory capability.

Decrements the SP by two, then stores the return address on the stack. The SP points to the high-order byte of the return address.

Decrements the SP by one, then stacks the current memory page value from the PPAGE register on the stack.

Writes a new page value supplied by the instruction to PPAGE and transfers control to the subroutine.

In indexed-indirect modes, the subroutine address and the PPAGE value are fetched from memory in the order M high byte, M low byte, and new PPAGE value.

Expanded-memory subroutines must be terminated by an RTC instruction, which restores the return address and PPAGE value from the stack.

# CLI

## Clear Interrupt Mask

# CLI

**Operation:** 0 ⇒ I bit

**Description:** Clears the I mask bit. This instruction is assembled as ANDCC #\$EF. The ANDCC instruction can be used to clear any combination of bits in the CCR in one operation.

When the I bit is cleared, interrupts are enabled. There is a 1-cycle (bus clock) delay in the clearing mechanism for the I bit so that, if interrupts were previously disabled, the next instruction after a CLI will always be executed, even if there was an interrupt pending prior to execution of the CLI instruction.

# DAA

## Decimal Adjust A

# DAA

**Description:** DAA adjusts the content of accumulator A and the state of the C status bit to represent the correct binary-coded-decimal sum and the associated carry when a BCD calculation has been performed. To execute DAA, the content of accumulator A, the state of the C status bit, and the state of the H status bit must all be the result of performing an ABA, ADD, or ADC on BCD operands, with or without an initial carry. The table shows DAA operation for all legal combinations of input operands. Columns 1 through 4 represent the results of ABA, ADC, or ADD operations on BCD operands. The correction factor in column 5 is added to the accumulator to restore the result of an operation on two BCD operands to a valid BCD value and to set or clear the C bit. All values are in hexadecimal.

1	2	3	4	5	6
Initial C Bit Value	Value of A[7:4]	Initial H Bit Value	Value of A[3:0]	Correction Factor	Corrected C Bit Value
0	0–9	0	0–9	00	0
0	0–8	0	A–F	06	0
0	0–9	1	0–3	06	0
0	A–F	0	0–9	60	1
0	9–F	0	A–F	66	1
0	A–F	1	0–3	66	1
1	0–2	0	0–9	60	1
1	0–2	0	A–F	66	1
1	0–3	1	0–3	66	1

**CCR Details:**

## DBEQ

Decrement and Branch if Equal to Zero

## DBEQ

**Operation:** (Counter) – 1 ⇒ Counter  
 If (Counter) = 0, then (PC) + \$0003 + Rel ⇒ PC

**Description:** Subtract one from the specified counter register A, B, D, X, Y, or SP. If the counter register has reached zero, execute a branch to the specified relative destination. The DBEQ instruction is encoded into three bytes of machine code including the 9-bit relative offset (–256 to +255 locations from the start of the next instruction).

IBEQ and TBEQ instructions are similar to DBEQ except that the counter is incremented or tested rather than being decremented. Bits 7 and 6 of the instruction postbyte are used to determine which operation is to be performed.

**CCR Details:**

# EMACS      Extended Multiply and Accumulate (Signed)      EMACS

## 16-Bit by 16-Bit to 32-Bit

**Operation:**  $(M_{(X)} : M_{(X+1)}) \times (M_{(Y)} : M_{(Y+1)}) + (M \sim M+3) \Rightarrow M \sim M+3$

**Description:** A 16-bit value is multiplied by a 16-bit value to produce a 32-bit intermediate result. This 32-bit intermediate result is then added to the content of a 32-bit accumulator in memory. EMACS is a signed integer operation. All operands and results are located in memory. When the EMACS instruction is executed, the first source operand is fetched from an address pointed to by X, and the second source operand is fetched from an address pointed to by index register Y. Before the instruction is executed, the X and Y index registers must contain values that point to the most significant bytes of the source operands. The most significant byte of the 32-bit result is specified by an extended address supplied with the instruction.

**CCR Details:**

<b>S</b>	<b>X</b>	<b>H</b>	<b>I</b>	<b>N</b>	<b>Z</b>	<b>V</b>	<b>C</b>

## EMAXD

Place Larger of Two  
Unsigned 16-Bit Values  
in Accumulator D

## EMAXD

**Operation:**  $\text{MAX} ((D), (M : M + 1)) \Rightarrow D$

**Description:** Subtracts an unsigned 16-bit value in memory from an unsigned 16-bit value in double accumulator D to determine which is larger, and leaves the larger of the two values in D. The Z status bit is set when the result of the subtraction is zero (the values are equal), and the C status bit is set when the subtraction requires a borrow (the value in memory is larger than the value in the accumulator). When C = 1, the value in D has been replaced by the value in memory.

The unsigned value in memory is accessed by means of indexed addressing modes, which allow a great deal of flexibility in specifying the address of the operand. Auto increment/decrement variations of indexed addressing facilitate finding the largest value in a list of values.

**CCR Details:**

S	X	H	I	N	Z	V	C
-	-	-	-	Δ	Δ	Δ	Δ

N: Set if MSB of result is set; cleared otherwise

# EMUL

## Extended Multiply 16-Bit by 16-Bit (Unsigned)

# EMUL

**Operation:**  $(D) \times (Y) \Rightarrow Y : D$

**Description:** An unsigned 16-bit value is multiplied by an unsigned 16-bit value to produce an unsigned 32-bit result. The first source operand must be loaded into 16-bit double accumulator D and the second source operand must be loaded into index register Y before executing the instruction. When the instruction is executed, the value in D is multiplied by the value in Y. The upper 16-bits of the 32-bit result are stored in Y and the low-order 16-bits of the result are stored in D.

The C status bit can be used to round the high-order 16 bits of the result.

**CCR Details:**

# ETBL

## Extended Table Lookup and Interpolate

# ETBL

**Operation:**  $(M : M + 1) + [(B) \times ((M + 2 : M + 3) - (M : M + 1))] \Rightarrow D$

**Description:** ETBL linearly interpolates one of 256 result values that fall between each pair of data entries in a lookup table stored in memory. Data entries in the table represent the y values of endpoints of equally-spaced line segments. Table entries and the interpolated result are 16-bit values. The result is stored in the D accumulator.

Before executing ETBL, an index register points to the table entry corresponding to the x value (X1 that is closest to, but less than or equal to, the desired lookup point (XL, YL). This defines the left end of a line segment and the right end is defined by the next data entry in the table. Prior to execution, accumulator B holds a binary fraction (radix left of MSB) representing the ratio of  $(XL - X1) \div (X2 - X1)$ .

The 16-bit unrounded result is calculated using the following expression:

$$D = Y1 + [(B) \times (Y2 - Y1)]$$

Where:

$$(B) = (XL - X1) \div (X2 - X1)$$

Y1 = 16-bit data entry pointed to by <effective address>

Y2 = 16-bit data entry pointed to by <effective address> + 2

The intermediate value  $[(B) \times (Y2 - Y1)]$  produces a 24-bit result with the radix point between bits 7 and 8. Any indexed addressing mode, except indirect modes or 9-bit and 16-bit offset modes, can be used to identify the first data point (X1, Y1). The second data point is the next table entry.

**CCR Details:**

# EXG

## Exchange Register Contents

# EXG

**Operation:** See table

**Description:** Exchanges the contents of registers specified in the instruction as shown below. Note that the order in which exchanges between 8-bit and 16-bit registers are specified affects the high byte of the 16-bit registers differently. Exchanges of D with A or B are ambiguous. Cases involving TMP2 and TMP3 are reserved, so some assemblers may not permit their use, but it is possible to generate these cases by using DC.B or DC.W assembler directives.

**CCR Details:**

S	X	H	I	N	Z	V	C	Or:	S	X	H	I	N	Z	V	C
-	-	-	-	-	-	-	-		Δ	↓	Δ	Δ	Δ	Δ	Δ	Δ

None affected, unless the CCR is the destination register. Condition codes take on the value of the corresponding source bits, except that the X mask bit cannot change from 0 to 1. Software can leave the X bit set, leave it cleared, or change it from 1 to 0, but it can be set only in response to any reset or by recognition of an  $\overline{XIRQ}$  interrupt.

# FDIV

## Fractional Divide

# FDIV

**Operation:**  $(D) \div (X) \Rightarrow X$ ; Remainder  $\Rightarrow D$

**Description:** Divides an unsigned 16-bit numerator in double accumulator D by an unsigned 16-bit denominator in index register X, producing an unsigned 16-bit quotient in X and an unsigned 16-bit remainder in D. If both the numerator and the denominator are assumed to have radix points in the same positions, the radix point of the quotient is to the left of bit 15. The numerator must be less than the denominator. In the case of overflow (denominator is less than or equal to the numerator) or division by zero, the quotient is set to \$FFFF, and the remainder is indeterminate.

FDIV is equivalent to multiplying the numerator by  $2^{16}$  and then performing 32 by 16-bit integer division. The result is interpreted as a binary-weighted fraction, which resulted from the division of a 16-bit integer by a larger 16-bit integer. A result of \$0001 corresponds to 0.000015, and \$FFFF corresponds to 0.9998. The remainder of an IDIV instruction can be resolved into a binary-weighted fraction by an FDIV instruction. The remainder of an FDIV instruction can be resolved into the next 16 bits of binary-weighted fraction by another FDIV instruction.

# GLDX

## Load Stack Index Register X from Global Memory

# GLDX

**Operation:**  $G(M : M + 1) \Rightarrow X$

**Description:** Loads the content of global memory location  $M : M + 1$  into index register X. The condition codes are set according to the data.

A global memory reference appends the contents of the GPAGE register to the most significant byte of the effective address to form a 23-bit address.

**CCR Details:**

# IBEQ

## Increment and Branch if Equal to Zero

# IBEQ

**Operation:** (Counter) + 1 ⇒ Counter  
 If (Counter) = 0, then (PC) + \$0003 + Rel ⇒ PC

**Description:** Add one to the specified counter register A, B, D, X, Y, or SP. If the counter register has reached zero, branch to the specified relative destination. The IBEQ instruction is encoded into three bytes of machine code including a 9-bit relative offset (–256 to +255 locations from the start of the next instruction).

DBEQ and TBEQ instructions are similar to IBEQ except that the counter is decremented or tested rather than being incremented. Bits 7 and 6 of the instruction postbyte are used to determine which operation is to be performed.

**CCR Details:**

S	X	H	I	N	Z	V	C

# IDIV

## Integer Divide

# IDIV

**Operation:**  $(D) \div (X) \Rightarrow X$ ; Remainder  $\Rightarrow D$

**Description:** Divides an unsigned 16-bit dividend in double accumulator D by an unsigned 16-bit divisor in index register X, producing an unsigned 16-bit quotient in X, and an unsigned 16-bit remainder in D. If both the divisor and the dividend are assumed to have radix points in the same positions, the radix point of the quotient is to the right of bit 0. In the case of division by zero, C is set, the quotient is set to \$FFFF, and the remainder is indeterminate.

**CCR Details:**

<b>S</b>	<b>X</b>	<b>H</b>	<b>I</b>	<b>N</b>	<b>Z</b>	<b>V</b>	<b>C</b>

IDIV	INH	18 10	0fffffffffff0	0fffffffffff0

# IDIVS

## Integer Divide (Signed)

# IDIVS

**Operation:** (D) ÷ (X) ⇒ X; Remainder ⇒ D

**Description:** Performs signed integer division of a signed 16-bit numerator in double accumulator D by a signed 16-bit denominator in index register X, producing a signed 16-bit quotient in X, and a signed 16-bit remainder in D. If division by zero is attempted, the values in D and X are not changed, C is set, and the values of the N, Z, and V status bits are undefined.

Other than division by zero, which is not legal and causes the C status bit to be set, the only overflow case is:

$$\frac{\$8000}{\$FFFF} = \frac{-32,768}{-1} = +32,768$$

But the highest positive value that can be represented in a 16-bit two's complement number is 32,767 (\$7FFF).

**CCR Details:**

<b>S</b>	<b>X</b>	<b>H</b>	<b>I</b>	<b>N</b>	<b>Z</b>	<b>V</b>	<b>C</b>
-	-	-	-	Δ	Δ	Δ	Δ

**N:** Set if MSB of result is set; cleared otherwise  
Undefined after overflow or division by zero

**Z:** Set if quotient is \$0000; cleared otherwise  
Undefined after overflow or division by zero

**V:** Set if the result was > \$7FFF or < \$8000; cleared otherwise  
Undefined after division by zero

**C:**  $\overline{X15} \cdot \overline{X14} \cdot \overline{X13} \cdot \overline{X12} \cdot \dots \cdot \overline{X3} \cdot \overline{X2} \cdot \overline{X1} \cdot \overline{X0}$

# INC

## Increment Memory

# INC

**Operation:** (M) + \$01 ⇒ M

**Description:** Add one to the content of memory location M.

The N, Z and V status bits are set or cleared according to the results of the operation. The C status bit is not affected by the operation, thus allowing the INC instruction to be used as a loop counter in multiple-precision computations.

When operating on unsigned values, only BEQ, BNE, LBEQ, and LBNE branches can be expected to perform consistently. When operating on two's complement values, all signed branches are available.

**CCR Details:**

S	X	H	I	N	Z	V	C

# JSR

## Jump to Subroutine

# JSR

**Operation:**  $(SP) - \$0002 \Rightarrow SP$   
 $RTN_H : RTN_L \Rightarrow M_{(SP)} : M_{(SP + 1)}$   
 Subroutine Address  $\Rightarrow PC$

**Description:** Sets up conditions to return to normal program flow, then transfers control to a subroutine. Uses the address of the instruction following the JSR as a return address.

Decrements the SP by two to allow the two bytes of the return address to be stacked.

Stacks the return address. The SP points to the high order byte of the return address.

Calculates an effective address according to the rules for extended, direct, or indexed addressing.

Jumps to the location determined by the effective address.

Subroutines are normally terminated with an RTS instruction, which restores the return address from the stack.

For SP relative auto pre/post decrement/increment indexed addressing modes, the effective address of the jump is calculated first, then SP adjustments associated with the stacking operation.

# LBGE

Long Branch if Greater Than or Equal to Zero

# LBGE

**Operation:** If  $N \oplus V = 0$ ,  $(PC) + \$0004 + Rel \Rightarrow PC$

For signed two's complement numbers, if (Accumulator)  $\geq$  Memory), then branch

**Description:** LBGE can be used to branch after subtracting or comparing signed two's complement values. After CMPA, CMPB, CPD, CPS, CPX, CPY, SBCA, SBCB, SUBA, SUBB, or SUBD, the branch occurs if the CPU12 register value is greater than or equal to the value in M. After CBA or SBA, the branch occurs if the value in B is greater than or equal to the value in A.

See [3.9 Relative Addressing Mode](#) for details of branch execution.

# LBLO

## Long Branch if Lower (Same as LBGS)

# LBLO

**Operation:** If  $C = 1$ , then  $(PC) + \$0004 + Rel \Rightarrow PC$

For unsigned binary numbers, if (Accumulator) < (Memory), then branch

**Description:** LBLO can be used to branch after subtracting or comparing unsigned values. After CMPA, CMPB, CPD, CPS, CPX, CPY, SUBA, SUBB, or SUBD, the branch occurs if the CPU12 register value is less than the value in M. After CBA or SBA, the branch occurs if the value in B is less than the value in A. LBLO should not be used for branching after instructions that do not affect the C bit, such as increment, decrement, load, store, test, clear, or complement.

See [3.9 Relative Addressing Mode](#) for details of branch execution.

# LBRA

## Long Branch Always

# LBRA

**Operation:**  $(PC) + \$0004 + Rel \Rightarrow PC$

**Description:** Unconditional branch to an address calculated as shown in the expression. Rel is a relative offset stored as a two's complement number in the second and third bytes of machine code corresponding to the long branch instruction.

Execution time is longer when a conditional branch is taken than when it is not, because the instruction queue must be refilled before execution resumes at the new address. Since the LBRA branch condition is always satisfied, the branch is always taken, and the instruction queue must always be refilled, so execution time is always the larger value.

See [3.9 Relative Addressing Mode](#) for details of branch execution.

LBRA <i>rel16</i>	REL	18 20 qq rr	OPPP	OPPP

# LBRN

Long Branch Never

# LBRN

**Operation:** (PC) + \$0004 ⇒ PC

**Description:** Never branches. LBRN is effectively a 4-byte NOP that requires three cycles to execute. LBRN is included in the instruction set to provide a complement to the LBRA instruction. The instruction is useful during program debug, to negate the effect of another branch instruction without disturbing the offset byte. A complement for LBRA is also useful in compiler implementations.

Execution time is longer when a conditional branch is taken than when it is not, because the instruction queue must be refilled before execution resumes at the new address. Since the LBRN branch condition is never satisfied, the branch is never taken, and the queue does not need to be refilled, so execution time is always the smaller value.

# LBVC

## Long Branch if Overflow Cleared

# LBVC

**Operation:** If  $V = 0$ , then  $(PC) + \$0004 + Rel \Rightarrow PC$

Simple branch

**Description:** Tests the V status bit and branches if  $V = 0$ .

LBVC causes a branch when a previous operation on two's complement binary values does not cause an overflow. That is, when LBVC follows a two's complement operation, a branch occurs when the result of the operation is valid.

See [3.9 Relative Addressing Mode](#) for details of branch execution.

# LEAS

## Load Stack Pointer with Effective Address

# LEAS

**Operation:** Effective Address  $\Rightarrow$  SP

**Description:** Loads the stack pointer with an effective address specified by the program. The effective address can be any indexed addressing mode operand address except an indirect address. Indexed addressing mode operand addresses are formed by adding an optional constant supplied by the program or an accumulator value to the current value in X, Y, SP, or PC. See [3.10 Indexed Addressing Modes](#) for more details.

LEAS does not alter condition code bits. This allows stack modification without disturbing CCR bits changed by recent arithmetic operations.

Operation is a bit more complex when LEAS is used with auto-increment or auto-decrement operand specifications and the SP is the referenced index register. The index register is loaded with what would have gone out to the address bus in the case of a load index instruction. In the case of a pre-increment or pre-decrement, the modification is made before the index register is loaded. In the case of a post-increment or post-decrement, modification would have taken effect after the address went out on the address bus, so post-modification does not affect the content of the index register.

In the unusual case where LEAS involves two different index registers and post-increment or post-decrement, both index registers are modified as demonstrated by the following example. Consider the instruction LEAS 4,Y+. First S is loaded with the value of Y, then Y is incremented by 4.

# LEAX

## Load X with Effective Address

# LEAX

**Operation:** Effective Address  $\Rightarrow$  X

**Description:** Loads index register X with an effective address specified by the program. The effective address can be any indexed addressing mode operand address except an indirect address. Indexed addressing mode operand addresses are formed by adding an optional constant supplied by the program or an accumulator value to the current value in X, Y, SP, or PC. See [3.10 Indexed Addressing Modes](#) for more details.

Operation is a bit more complex when LEAX is used with auto-increment or auto-decrement operand specifications and index register X is the referenced index register. The index register is loaded with what would have gone out to the address bus in the case of a load indexed instruction. In the case of a pre-increment or pre-decrement, the modification is made before the index register is loaded. In the case of a post-increment or post-decrement, modification would have taken effect after the address went out on the address bus, so post-modification does not affect the content of the index register.

In the unusual case where LEAX involves two different index registers and post-increment and post-decrement, both index registers are modified as demonstrated by the following example. Consider the instruction LEAX 4,Y+. First X is loaded with the value of Y, then Y is incremented by 4.

# LEAY

## Load Y with Effective Address

# LEAY

**Operation:** Effective Address  $\Rightarrow$  Y

**Description:** Loads index register Y with an effective address specified by the program. The effective address can be any indexed addressing mode operand address except an indirect address. Indexed addressing mode operand addresses are formed by adding an optional constant supplied by the program or an accumulator value to the current value in X, Y, SP, or PC. See [3.10 Indexed Addressing Modes](#) for more details.

Operation is a bit more complex when LEAY is used with auto-increment or auto-decrement operand specifications and index register Y is the referenced index register. The index register is loaded with what would have gone out to the address bus in the case of a load indexed instruction. In the case of a pre-increment or pre-decrement, the modification is made before the index register is loaded. In the case of a post-increment or post-decrement, modification would have taken effect after the address went out on the address bus, so post-modification does not affect the content of the index register.

In the unusual case where LEAY involves two different index registers and post-increment and post-decrement, both index registers are modified as demonstrated by the following example. Consider the instruction LEAY 4,X+. First Y is loaded with the value of X, then X is incremented by 4.

# LSRX

## Logical Shift Register X to Right

# LSRX

**Operation:**

**Description:** Shifts all bits of index register X one place to the right. Bit 15 is loaded with 0. The C status bit is loaded from the least significant bit of X.

**CCR Details:**

S	X	H	I	N	Z	V	C
-	-	-	-	0	Δ	Δ	Δ

N: 0; cleared

Z: Set if result is \$0000; cleared otherwise

V:  $N \oplus C = [N \cdot \bar{C}] + [\bar{N} \cdot C]$  (for N and C after the shift)  
Set if (N is set and C is cleared) or (N is cleared and C is set); cleared otherwise (for values of N and C after the shift)

C: X0  
Set if the LSB of X was set before the shift; cleared otherwise

## MAXA

Place Larger of Two Unsigned 8-Bit Values  
in Accumulator A

## MAXA

**Operation:** MAX ((A), (M))  $\Rightarrow$  A

**Description:** Subtracts an unsigned 8-bit value in memory from an unsigned 8-bit value in accumulator A to determine which is larger and leaves the larger of the two values in A. The Z status bit is set when the result of the subtraction is zero (the values are equal), and the C status bit is set when the subtraction requires a borrow (the value in memory is larger than the value in the accumulator). When C = 1, the value in A has been replaced by the value in memory.

The unsigned value in memory is accessed by means of indexed addressing modes, which allow a great deal of flexibility in specifying the address of the operand. Auto increment/decrement variations of indexed addressing facilitate finding the largest value in a list of values.

**CCR Details:**

S	X	H	I	N	Z	V	C
-	-	-	-	$\Delta$	$\Delta$	$\Delta$	$\Delta$

N: Set if MSB of result is set; cleared otherwise

Z: Set if result is \$00; cleared otherwise

V:  $A7 \cdot \overline{M7} \cdot \overline{R7} + \overline{A7} \cdot M7 \cdot R7$

Set if a two's complement overflow resulted from the operation; cleared otherwise

C:  $\overline{A7} \cdot M7 + M7 \cdot R7 + R7 \cdot \overline{A7}$

Set if the value of the content of memory is larger than the value of the accumulator; cleared otherwise

Condition codes reflect internal subtraction (R = A – M)

# MEM

## Determine Grade of Membership (Fuzzy Logic)

# MEM

**Operation:** Grade of Membership  $\Rightarrow M_{(Y)}$   
 $(Y) + \$0001 \Rightarrow Y$   
 $(X) + \$0004 \Rightarrow X$

**Description:** Before executing MEM, initialize A, X, and Y. Load A with the current crisp value of a system input variable. Load Y with the fuzzy input RAM location where the grade of membership is to be stored. Load X with the first address of a 4-byte data structure that describes a trapezoidal membership function. The data structure consists of:

- Point\_1 — The x-axis starting point for the leading side (at  $M_X$ )
- Slope\_1 — The slope of the leading side (at  $M_{X+1}$ )
- Point\_2 — The x-axis position of the rightmost point (at  $M_{X+2}$ )
- Slope\_2 — The slope of the trailing side (at  $M_{X+3}$ ); the right side slopes up and to the left from point\_2

A slope\_1 or slope\_2 value of \$00 is a special case in which the membership function either starts with a grade of \$FF at input = point\_1, or ends with a grade of \$FF at input = point\_2 (infinite slope).

During execution, the value of A remains unchanged. X is incremented by four and Y is incremented by one.

# MOVB

## Immediate-to-Memory Byte Move (8 Bit)

# MOVB

**Operation:** # ⇒ M

**Description:** Moves the immediate value # to memory location M.

Move byte instructions specify the source first and destination second in the object code for an immediate value source and an extended addressing mode destination. Move byte instructions using immediate values for the source and indexed addressing modes for the destination have the destination index code (xb) specified before the source value for HCS12 and HC12 compatibility.

**CCR Details:**

# MOVB

## Memory-to-Memory Byte Move IDX Source (8 Bit)

# MOVB

**Operation:**  $(M_1) \Rightarrow M_2$   
 IDX Source  $\Rightarrow$  Address Mode Destination

**Description:** Moves the content of one 8-bit memory location to another 8-bit memory location. The content of the source memory location is not changed.

Move byte instructions specify the source first and destination second in the object code for all indexed addressing mode sources.

For auto pre/post decrement/increment indexed addressing modes, the effective address of the source is calculated first and the source index register is updated appropriately, then the destination effective address is calculated.

A PC offset must be applied to the source address when using PC relative index addressing for the source operand and any of the three destination index addressing modes listed below:

IDX1: +1

IDX2: +2

[IDX2]: +2

These offsets compensate for the variable instruction length and are needed to identify the location of the instruction immediately following the MOVB instruction.

EXT Source  $\Rightarrow$  Address Mode Destination

**Description:** Moves the content of one 16-bit location in memory to another 16-bit location in memory. The content of the source memory location is not changed.

Move word instructions specify the source first and destination second in the object code for an extended addressing mode source and an extended addressing mode destination. Move word instructions using extended addressing for the source and indexed addressing modes for the destination have the destination index code (xb) specified before the source value for HCS12 and HC12 compatibility.

**CCR Details:**

1. The first operand in the source code statement specifies the source for the move.

2. The IDX destination code is listed before the source for backwards compatibility.

## MOVW

Memory-to-Memory Word Move  
 IDX Source (16 Bit)

## MOVW

**Operation:**  $(M : M + 1_1) \Rightarrow M : M + 1_2$   
 IDX Source  $\Rightarrow$  Address Mode Destination

**Description:** Moves the content of one 16-bit location in memory to another 16-bit location in memory. The content of the source memory location is not changed.

Move word instructions specify the source first and destination second in the object code for all indexed addressing mode sources.

For auto pre/post decrement/increment indexed addressing modes, the effective address of the source is calculated first and the source index register is updated appropriately, then the destination effective address is calculated.

A PC offset must be applied to the source address when using PC relative index addressing for the source operand and any of the three destination index addressing modes listed below:

- IDX1: +1
- IDX2: +2
- [IDX2]: +2

These offsets compensate for the variable instruction length and are needed to identify the location of the instruction immediately following the MOVW instruction.

# NOP

Null Operation

# NOP

**Operation:** No operation

**Description:** This single-byte instruction increments the PC and does nothing else. No other CPU12 registers are affected. NOP is typically used to produce a time delay, although some software disciplines discourage CPU12 frequency-based time delays. During debug, NOP instructions are sometimes used to temporarily replace other machine code instructions, thus disabling the replaced instruction(s).

# REV

## Fuzzy Logic Rule Evaluation

# REV

**Operation:** MIN-MAX Rule Evaluation

**Description:** Performs an unweighted evaluation of a list of rules, using fuzzy input values to produce fuzzy outputs. REV can be interrupted, so it does not adversely affect interrupt latency.

The REV instruction uses an 8-bit offset from a base address stored in index register Y to determine the address of each fuzzy input and fuzzy output. For REV to execute correctly, each rule in the knowledge base must consist of a table of 8-bit antecedent offsets followed by a table of 8-bit consequent offsets. The value \$FE marks boundaries between antecedents and consequents and between successive rules. The value \$FF marks the end of the rule list. REV can evaluate any number of rules with any number of inputs and outputs.

Beginning with the address pointed to by the first rule antecedent, REV evaluates each successive fuzzy input value until it encounters an \$FE separator. Operation is similar to that of a MINA instruction. The smallest input value is the truth value of the rule. Then, beginning with the address pointed to by the first rule consequent, the truth value is compared to each successive fuzzy output value until another \$FE separator is encountered; if the truth value is greater than the current output value, it is written to the output. Operation is similar to that of a MAXM instruction. Rules are processed until an \$FF terminator is encountered.

Before executing REV, perform these set up operations.

- X must point to the first 8-bit element in the rule list.
- Y must point to the base address for fuzzy inputs and fuzzy outputs.
- A must contain the value \$FF, and the CCR V bit must = 0. (LDAA #\$FF places the correct value in A and clears V.)
- Clear fuzzy outputs to 0s.

Index register X points to the element in the rule list that is being evaluated. X is automatically updated so that execution can resume correctly if the instruction is interrupted. When execution is complete, X points to the next address after the \$FF separator at the end of the rule list.

# REV

## Fuzzy Logic Rule Evaluation (Continued)

# REV

Index register Y points to the base address for the fuzzy inputs and fuzzy outputs. The value in Y does not change during execution.

Accumulator A holds intermediate results. During antecedent processing, a MIN function compares each fuzzy input to the value stored in A, and writes the smaller of the two to A. When all antecedents have been evaluated, A contains the smallest input value. This is the truth value used during consequent processing. Accumulator A must be initialized to \$FF for the MIN function to evaluate the inputs of the first rule correctly. For subsequent rules, the value \$FF is written to A when an \$FE marker is encountered. At the end of execution, accumulator A holds the truth value for the last rule.

The V status bit signals whether antecedents (0) or consequents (1) are being processed. V must be initialized to 0 for processing to begin with the antecedents of the first rule. Once execution begins, the value of V is automatically changed as \$FE separators are encountered. At the end of execution, V should equal 1, because the last element before the \$FF end marker should be a rule consequent. If V is equal to 0 at the end of execution, the rule list is incorrect.

Fuzzy outputs must be cleared to \$00 before processing begins in order for the MAX algorithm used during consequent processing to work correctly. Residual output values would cause incorrect comparison.

Refer to **Section 9. Fuzzy Logic Support** for details.

**CCR Details:**

REV (replace comma if interrupted)	Special	18 3A	Orf(t,tx)0 ff + Orf(t,	Orf(t,tx)0 ff + Orf(t,

1. The 3-cycle loop in parentheses is executed once for each element in the rule list. When an interrupt occurs, there is a 2-cycle exit sequence, a 4-cycle re-entry sequence, then execution resumes with a prefetch of the last antecedent or consequent being processed at the time of the interrupt.

# RE VW

## Fuzzy Logic Rule Evaluation (Weighted)

# RE VW

**Operation:** MIN-MAX Rule Evaluation with Optional Rule Weighting

**Description:** RE VW performs either weighted or unweighted evaluation of a list of rules, using fuzzy inputs to produce fuzzy outputs. RE VW can be interrupted, so it does not adversely affect interrupt latency.

For RE VW to execute correctly, each rule in the knowledge base must consist of a table of 16-bit antecedent pointers followed by a table of 16-bit consequent pointers. The value \$FFFE marks boundaries between antecedents and consequents, and between successive rules. The value \$FFFF marks the end of the rule list. RE VW can evaluate any number of rules with any number of inputs and outputs.

Setting the C status bit enables weighted evaluation. To use weighted evaluation, a table of 8-bit weighting factors, one per rule, must be stored in memory. Index register Y points to the weighting factors.

Beginning with the address pointed to by the first rule antecedent, RE VW evaluates each successive fuzzy input value until it encounters an \$FFFE separator. Operation is similar to that of a MINA instruction. The smallest input value is the truth value of the rule. Next, if weighted evaluation is enabled, a computation is performed, and the truth value is modified. Then, beginning with the address pointed to by the first rule consequent, the truth value is compared to each successive fuzzy output value until another \$FFFE separator is encountered; if the truth value is greater than the current output value, it is written to the output. Operation is similar to that of a MAXM instruction. Rules are processed until an \$FFFF terminator is encountered.

Perform these set up operations before execution:

- X must point to the first 16-bit element in the rule list.
- A must contain the value \$FF, and the CCR V bit must = 0 (LDAA #\$FF places the correct value in A and clears V).
- Clear fuzzy outputs to 0s.
- Set or clear the CCR C bit. When weighted evaluation is enabled, Y must point to the first item in a table of 8-bit weighting factors.

# REVW

## Fuzzy Logic Rule Evaluation (Weighted) (Continued)

# REVW

Index register X points to the element in the rule list that is being evaluated. X is automatically updated so that execution can resume correctly if the instruction is interrupted. When execution is complete, X points to the address after the \$FFFF separator at the end of the rule list.

Index register Y points to the weighting factor being used. Y is automatically updated so that execution can resume correctly if the instruction is interrupted. When execution is complete, Y points to the last weighting factor used. When weighting is not used ( $C = 0$ ), Y is not changed.

Accumulator A holds intermediate results. During antecedent processing, a MIN function compares each fuzzy input to the value stored in A and writes the smaller of the two to A. When all antecedents have been evaluated, A contains the smallest input value. For unweighted evaluation, this is the truth value used during consequent processing. For weighted evaluation, the value in A is multiplied by the quantity (Rule Weight + 1) and the upper eight bits of the result replace the content of A. Accumulator A must be initialized to \$FF for the MIN function to evaluate the inputs of the first rule correctly. For subsequent rules, the value \$FF is automatically written to A when an \$FFFE marker is encountered. At the end of execution, accumulator A holds the truth value for the last rule.

The V status bit signals whether antecedents (0) or consequents (1) are being processed. V must be initialized to 0 for processing to begin with the antecedents of the first rule. Once execution begins, the value of V is automatically changed as \$FFFE separators are encountered. At the end of execution, V should equal 1, because the last element before the \$FF end marker should be a rule consequent. If V is equal to 0 at the end of execution, the rule list is incorrect.

Fuzzy outputs must be cleared to \$00 before processing begins in order for the MAX algorithm used during consequent processing to work correctly. Residual output values would cause incorrect comparison.

Refer to **Section 9. Fuzzy Logic Support** for details.

# ROLX Rotate X Left through Carry ROLX

**Operation:**

**Description:** Shifts all bits of index register X one place to the left. Bit 0 is loaded from the C status bit. The C bit is loaded from the most significant bit of X. Rotate operations include the carry bit to allow extension of shift and rotate operations to multiple words.

**CCR Details:**

S	X	H	I	N	Z	V	C
-	-	-	-	Δ	Δ	Δ	Δ

- N: Set if MSB of result is set; cleared otherwise
- Z: Set if result is \$0000; cleared otherwise
- V:  $N \oplus C = [N \cdot \bar{C}] + [\bar{N} \cdot C]$  (for N and C after the shift)  
Set if (N is set and C is cleared) or (N is cleared and C is set);  
cleared otherwise (for values of N and C after the shift)
- C: X15  
Set if the MSB of X was set before the shift; cleared otherwise

# ROR

## Rotate Right Memory

# ROR

**Operation:**

**Description:**

Shifts all bits of memory location M one place to the right. Bit 7 is loaded from the C status bit. The C bit is loaded from the least significant bit of M. Rotate operations include the carry bit to allow extension of shift and rotate operations to multiple bytes. For example, to shift a 24-bit value one bit to the right, the sequence LSR HIGH, ROR MID, and ROR LOW could be used where LOW, MID, and HIGH refer to the low-order, middle, and high-order bytes of the 24-bit value, respectively.

**CCR Details:**

S	X	H	I	N	Z	V	C
-	-	-	-	Δ	Δ	Δ	Δ

# RTC

## Return from Call

# RTC

**Operation:**  $M_{(SP)} \Rightarrow PPAGE$   
 $(SP) + \$0001 \Rightarrow SP$   
 $(M_{(SP)} : M_{(SP+1)}) \Rightarrow PC_H : PC_L$   
 $(SP) + \$0002 \Rightarrow SP$

**Description:** Terminates subroutines in expanded memory invoked by the CALL instruction. Returns execution flow from the subroutine to the calling program. The program overlay page (PPAGE) register and the return address are restored from the stack; program execution continues at the restored address. For code compatibility purposes, CALL and RTC also execute correctly in devices that do not have expanded memory capability.

**CCR Details:**

<b>S</b>	<b>X</b>	<b>H</b>	<b>I</b>	<b>N</b>	<b>Z</b>	<b>V</b>	<b>C</b>

# RTI

## Return from Interrupt

# RTI

**Operation:**  $(M_{(SP)} : M_{(SP+1)}) \Rightarrow CCR_H : CCR_L; (SP) + \$0002 \Rightarrow SP$   
 $(M_{(SP)} : M_{(SP+1)}) \Rightarrow B : A; (SP) + \$0002 \Rightarrow SP$   
 $(M_{(SP)} : M_{(SP+1)}) \Rightarrow X_H : X_L; (SP) + \$0004 \Rightarrow SP$   
 $(M_{(SP)} : M_{(SP+1)}) \Rightarrow PC_H : PC_L; (SP) - \$0002 \Rightarrow SP$   
 $(M_{(SP)} : M_{(SP+1)}) \Rightarrow Y_H : Y_L; (SP) + \$0004 \Rightarrow SP$

**Description:** Restores system context after interrupt service processing is completed. The condition codes, accumulators B and A, index register X, the PC, and index register Y are restored to a state pulled from the stack. The X mask bit may be cleared as a result of an RTI instruction, but cannot be set if it was cleared prior to execution of the RTI instruction.

If another interrupt is pending when RTI has finished restoring registers from the stack, the SP is adjusted to preserve stack content, and the new vector is fetched. This operation is functionally identical to the same operation in the M68HC11, where registers actually are re-stacked, but is faster.

**CCR Details:**

<b>S</b>	<b>X</b>	<b>H</b>	<b>I</b>	<b>N</b>	<b>Z</b>	<b>V</b>	<b>C</b>
Δ	↓	Δ	Δ	Δ	Δ	Δ	Δ

Condition codes take on the value pulled from the stack, except that the X mask bit cannot change from 0 to 1. Software can leave the X bit set, leave it cleared, or change it from 1 to 0, but it can be set only by a reset or by recognition of an  $\overline{XIRQ}$  interrupt.

# SEX

## Sign Extend into 16-Bit Register

# SEX

**Operation:** If r1 bit 7 = 0, then \$00 : (r1) ⇒ r3  
 If r1 bit 7 = 1, then \$FF : (r1) ⇒ r3  
 If r2 bit 15 = 0, then \$0000 ⇒ r3  
 If r2 bit 15 = 1, then \$FFFF ⇒ r3

**Description:** This instruction is an alternate mnemonic for the TFR r1,r3 or TFR r2,r3 instructions, where r1 is an 8-bit register, and r2 and r3 are 16-bit registers. The result in r3 is the 16-bit sign extended representation of the original two's complement number in r1 or r2. The content of r1 or r2 is unchanged in all cases except that of SEX A,D (D is A : B).

 (SP) – \$0002 ⇒ SP; CCR<sub>H</sub> : CCR<sub>L</sub> ⇒ (M<sub>(SP)</sub> : M<sub>(SP+1)</sub>)  
 Stop All Clocks

**Description:** When the S control bit is set, STOP is disabled and operates like a 2-cycle NOP instruction. When the S bit is cleared, STOP stacks CPU12 context, stops all system clocks, and puts the device in standby mode.

Standby operation minimizes system power consumption. The contents of registers and the states of I/O pins remain unchanged.

Asserting the  $\overline{\text{RESET}}$ ,  $\overline{\text{XIRQ}}$ , or  $\overline{\text{IRQ}}$  signals ends standby mode. Stacking on entry to STOP allows the CPU12 to recover quickly when an interrupt is used, provided a stable clock is applied to the device. If the system uses a clock reference crystal that also stops during low-power mode, crystal startup delay lengthens recovery time.

If  $\overline{\text{XIRQ}}$  is asserted while the X mask bit = 0 ( $\overline{\text{XIRQ}}$  interrupts enabled), execution resumes with a vector fetch for the  $\overline{\text{XIRQ}}$  interrupt. While the X mask bit = 1 ( $\overline{\text{XIRQ}}$  interrupts disabled), a 2-cycle recovery sequence is used to adjust the instruction queue and the stack pointer, and execution continues with the next instruction after STOP.

# SWI

## Software Interrupt

# SWI

**Operation:**  $(SP) - \$0002 \Rightarrow SP; RTN_H : RTN_L \Rightarrow (M_{(SP)} : M_{(SP+1)})$   
 $(SP) - \$0002 \Rightarrow SP; Y_H : Y_L \Rightarrow (M_{(SP)} : M_{(SP+1)})$   
 $(SP) - \$0002 \Rightarrow SP; X_H : X_L \Rightarrow (M_{(SP)} : M_{(SP+1)})$   
 $(SP) - \$0002 \Rightarrow SP; B : A \Rightarrow (M_{(SP)} : M_{(SP+1)})$   
 $(SP) - \$0002 \Rightarrow SP; CCR_H : CCR_L \Rightarrow (M_{(SP)} : M_{(SP+1)})$   
 $1 \Rightarrow I$   
 $(SWI\ Vector) \Rightarrow PC$

**Description:** Causes an interrupt without an external interrupt service request. Uses the address of the next instruction after SWI as a return address. Stacks the return address, index registers Y and X, accumulators B and A, and the CCR, decrementing the SP before each item is stacked. The I mask bit is then set, the PC is loaded with the SWI vector, and instruction execution resumes at that location. SWI is not affected by the I mask bit. Refer to **Section 7. Exception Processing** for more information.

**CCR Details:**

S	X	H	I	N	Z	V	C

SWI	INH	3F	VSPSSPSSP <sup>(1)</sup>	VSPSSPSsP <sup>(1)</sup>

1. The CPU12 also uses the SWI processing sequence for hardware interrupts and unimplemented opcode traps. A variation of the sequence ( $V\bar{E}PPP$ ) is used for resets.

# TAB

## Transfer from Accumulator A to Accumulator B

# TAB

**Operation:** (A) ⇒ B

**Description:** Moves the content of accumulator A to accumulator B. The former content of B is lost; the content of A is not affected. Unlike the general transfer instruction TFR A,B which does not affect condition codes, the TAB instruction affects the N, Z, and V status bits for compatibility with M68HC11.

**CCR Details:**

			HCS12X	HCS12
TAB	INH	18 0E	00	00

# TAP

## Transfer from Accumulator A to Condition Code Register

# TAP

**Operation:** (A) ⇒ CCR<sub>L</sub>

**Description:** Transfers the logic states of bits [7:0] of accumulator A to the corresponding bit positions of the CCR. The content of A remains unchanged. The X mask bit can be cleared as a result of a TAP, but cannot be set if it was cleared prior to execution of the TAP. If the I bit is cleared, there is a 1-cycle delay before the system allows interrupt requests. This prevents interrupts from occurring between instructions in the sequences CLI, WAI and CLI, SEI.

This instruction is accomplished with the TFR A,CCR instruction. For compatibility with the M68HC11, the mnemonic TAP is translated by the assembler.

**CCR Details:**

<b>S</b>	<b>X</b>	<b>H</b>	<b>I</b>	<b>N</b>	<b>Z</b>	<b>V</b>	<b>C</b>
Δ	↓	Δ	Δ	Δ	Δ	Δ	Δ

Condition codes take on the value of the corresponding bit of accumulator A, except that the X mask bit cannot change from 0 to 1. Software can leave the X bit set, leave it cleared, or change it from 1 to 0, but it can only be set by a reset or by recognition of an  $\overline{XIRQ}$  interrupt.

# TBEQ

Test and Branch if Equal to Zero

# TBEQ

**Operation:** If (Counter) = 0, then (PC) + \$0003 + Rel  $\Rightarrow$  PC

**Description:** Tests the specified counter register A, B, D, X, Y, or SP. If the counter register is zero, branches to the specified relative destination. TBEQ is encoded into three bytes of machine code including a 9-bit relative offset (–256 to +255 locations from the start of the next instruction).

DBEQ and IBEQ instructions are similar to TBEQ, except that the counter is decremented or incremented rather than simply being tested. Bits 7 and 6 of the instruction postbyte are used to determine which operation is to be performed.

**CCR Details:**

# TBL

## Table Lookup and Interpolate

# TBL

**Operation:**  $(M) + [(B) \times ((M+1) - (M))] \Rightarrow A$

**Description:** Linearly interpolates one of 256 result values that fall between each pair of data entries in a lookup table stored in memory. Data entries in the table represent the Y values of endpoints of equally spaced line segments. Table entries and the interpolated result are 8-bit values. The result is stored in accumulator A.

Before executing TBL, an index register points to the table entry corresponding to the X value (X1) that is closest to, but less than or equal to, the desired lookup point (XL, YL). This defines the left end of a line segment and the right end is defined by the next data entry in the table. Prior to execution, accumulator B holds a binary fraction (radix point to left of MSB), representing the ratio  $(XL - X1) \div (X2 - X1)$ .

The 8-bit unrounded result is calculated using the following expression:

$$A = Y1 + [(B) \times (Y2 - Y1)]$$

Where

$$(B) = (XL - X1) \div (X2 - X1)$$

Y1 = 8-bit data entry pointed to by <effective address>

Y2 = 8-bit data entry pointed to by <effective address> + 1

The intermediate value  $[(B) \times (Y2 - Y1)]$  produces a 16-bit result with the radix point between bits 7 and 8. Any indexed addressing mode referenced to X, Y, SP, or PC, except indirect modes or 9-bit and 16-bit offset modes, can be used to identify the first data point (X1, Y1). The second data point is the next table entry.

**CCR Details:**

# TBNE

Test and Branch if Not Equal to Zero

# TBNE

**Operation:** If (Counter)  $\neq$  0, then (PC) + \$0003 + Rel  $\Rightarrow$  PC

**Description:** Tests the specified counter register A, B, D, X, Y, or SP. If the counter register is not zero, branches to the specified relative destination. TBNE is encoded into three bytes of machine code including a 9-bit relative offset (–256 to +255 locations from the start of the next instruction).

DBNE and IBNE instructions are similar to TBNE, except that the counter is decremented or incremented rather than simply being tested. Bits 7 and 6 of the instruction postbyte are used to determine which operation is to be performed.

**CCR Details:**

# TFR

## Transfer Register Content to Another Register

# TFR

**Operation:** See table.

**Description:** Transfers the content of a source register to a destination register specified in the instruction. The order in which transfers between 8-bit and 16-bit registers are specified affects the high byte of the 16-bit registers differently. Cases involving TMP2 and TMP3 are reserved for Motorola use, so some assemblers may not permit their use. It is possible to generate these cases by using DC.B or DC.W assembler directives.

**CCR Details:**

S	X	H	I	N	Z	V	C
-	-	-	-	-	-	-	-

Or:

S	X	H	I	N	Z	V	C
Δ	↓	Δ	Δ	Δ	Δ	Δ	Δ

None affected, unless the CCR is the destination register. Condition codes take on the value of the corresponding source bits, except that the X mask bit cannot change from 0 to 1. Software can leave the X bit set, leave it cleared, or change it from 1 to 0, but it can be set only by a reset or by recognition of an  $\overline{XIRQ}$  interrupt.

# TPA

## Transfer from Condition Code Register to Accumulator A

# TPA

**Operation:**  $(CCR_L) \Rightarrow A$

**Description:** Transfers the content of the condition code register to corresponding bit positions of accumulator A. The CCR remains unchanged.

This mnemonic is implemented by the TFR CCR,A instruction. For compatibility with the M68HC11, the mnemonic TPA is translated into the TFR CCR,A instruction by the assembler.

**CCR Details:**

# TRAP

## Unimplemented Opcode Trap

# TRAP

**Operation:** (SP) – \$0002 ⇒ SP; RTN<sub>H</sub> : RTN<sub>L</sub> ⇒ (M<sub>(SP)</sub> : M<sub>(SP+1)</sub>)  
 (SP) – \$0002 ⇒ SP; Y<sub>H</sub> : Y<sub>L</sub> ⇒ (M<sub>(SP)</sub> : M<sub>(SP+1)</sub>)  
 (SP) – \$0002 ⇒ SP; X<sub>H</sub> : X<sub>L</sub> ⇒ (M<sub>(SP)</sub> : M<sub>(SP+1)</sub>)  
 (SP) – \$0002 ⇒ SP; B : A ⇒ (M<sub>(SP)</sub> : M<sub>(SP+1)</sub>)  
 (SP) – \$0002 ⇒ SP; CCR<sub>H</sub> : CCR<sub>L</sub> ⇒ (M<sub>(SP)</sub> : M<sub>(SP+1)</sub>)  
 1 ⇒ I  
 (Trap Vector) ⇒ PC

**Description:** Traps unimplemented opcodes. There are opcodes in all 256 positions in the page 1 opcode map, but only 54 of the 256 positions on page 2 of the opcode map are used. If the CPU12 attempts to execute one of the unimplemented opcodes on page 2, an opcode trap interrupt occurs. Unimplemented opcode traps are essentially interrupts that share the \$FFF8:\$FFF9 interrupt vector.

TRAP uses the next address after the unimplemented opcode as a return address. It stacks the return address, index registers Y and X, accumulators B and A, and the CCR, automatically decrementing the SP before each item is stacked. The I mask bit is then set, the PC is loaded with the trap vector, and instruction execution resumes at that location. This instruction is not maskable by the I bit. Refer to **Section 7. Exception Processing** for more information.

# TST

## Test Memory

# TST

**Operation:** (M) – \$00

**Description:** Subtracts \$00 from the content of memory location M and sets the condition codes accordingly.

The subtraction is accomplished internally without modifying M.

The TST instruction provides limited information when testing unsigned values. Since no unsigned value is less than zero, BLO and BLS have no utility following TST. While BHI can be used after TST, it performs the same function as BNE, which is preferred. After testing signed values, all signed branches are available.

**CCR Details:**

 (SP) – \$0002 ⇒ SP; B : A ⇒ (M<sub>(SP)</sub> : M<sub>(SP+1)</sub>)  
 (SP) – \$0002 ⇒ SP; CCR<sub>H</sub> : CCR<sub>L</sub> ⇒ (M<sub>(SP)</sub> : M<sub>(SP+1)</sub>)  
 Stop CPU12 Clocks

**Description:** Puts the CPU12 into a wait state. Uses the address of the instruction following WAI as a return address. Stacks the return address, index registers Y and X, accumulators B and A, and the CCR, decrementing the SP before each item is stacked.

The CPU12 then enters a wait state for an integer number of bus clock cycles. During the wait state, CPU12 clocks are stopped, but other MCU clocks can continue to run. The CPU12 leaves the wait state when it senses an interrupt that has not been masked.

If XIRQ is asserted while the X mask bit = 0 (XIRQ interrupts enabled), execution resumes with a vector fetch for the XIRQ interrupt. While the X mask bit = 1 (XIRQ interrupts disabled), a 2-cycle recovery sequence is used to adjust the instruction queue and the stack pointer, and execution continues with the next instruction after WAI.

## WAV

### Weighted Average

## WAV

**Operation:** Do until B = 0, leave SOP in Y : D, SOW in X

Partial Product = (M pointed to by X) × (M pointed to by Y)  
 Sum-of-Products (24-bit SOP) = Previous SOP + Partial Product  
 Sum-of-Weights (16-bit SOW) = Previous SOW + (M pointed to by Y)  
 (X) + \$0001 ⇒ X; (Y) + \$0001 ⇒ Y  
 (B) – \$01 ⇒ B

**Description:** Performs weighted average calculations on values stored in memory. Uses indexed (X) addressing mode to reference one source operand list, and indexed (Y) addressing mode to reference a second source operand list. Accumulator B is used as a counter to control the number of elements to be included in the weighted average.

For each pair of data points, a 24-bit sum of products (SOP) and a 16-bit sum of weights (SOW) is accumulated in temporary registers. When B reaches zero (no more data pairs), the SOP is placed in Y : D. The SOW is placed in X. To arrive at the final weighted average, divide the content of Y : D by X by executing an EDIV after the WAV.

This instruction can be interrupted. If an interrupt occurs during WAV execution, the intermediate results (six bytes) are stacked in the order SOW<sub>[15:0]</sub>, SOP<sub>[15:0]</sub>, \$00:SOP<sub>[23:16]</sub> before the interrupt is processed. The wavr pseudo-instruction is used to resume execution after an interrupt. The mechanism is re-entrant. New WAV instructions can be started and interrupted while a previous WAV instruction is interrupted.

This instruction is often used in fuzzy logic rule evaluation. Refer to **Section 9. Fuzzy Logic Support** for more information.

## Section 7. Exception Processing

### 7.1 Introduction

Exceptions are events that require processing outside the normal flow of instruction execution. This section describes exceptions and the way each is handled.

### 7.2 Types of Exceptions

Central processor unit (CPU12) exceptions include:

- Resets
  - System reset :
    - $\overline{\text{RESET}}$  pin
    - Power On reset
    - Low Voltage reset
    - Illegal address reset (S12X only)
  - Clock monitor reset
  - COP watchdog reset
- An unimplemented opcode trap
- A software interrupt instruction (SWI) or BDM vector request
- Non-maskable (X-bit) interrupts
- Non-maskable (I-bit) interrupts

Each exception has an associated 16-bit vector, which points to the memory location where the routine that handles the exception is located. As shown in [Table 7-1](#), vectors are stored in the upper bytes of the standard 64-Kbyte address map.

The six highest vector addresses are used for resets and unmaskable interrupt sources. The remaining vectors are used for maskable

interrupts. All vectors must be programmed to point to the address of the appropriate service routine.

**Table 7-1. CPU12 Exception Vector Map<sup>(1)</sup>**

Vector Address <sup>(2)</sup>	Source
\$FFFE	System reset
\$FFFC	Clock Monitor reset
\$FFFA	COP Watchdog reset
(Vector Base <sup>(3)</sup> + \$F8)	Unimplemented opcode trap
(Vector Base + \$F6)	Software interrupt instruction (SWI) or BDM vector request
(Vector Base + \$F4)	$\overline{XIRQ}$ signal
(Vector Base + \$F2)	$\overline{IRQ}$ signal
(Vector Base + \$F0...\$10)	Device-specific interrupt sources (HCS12X)
\$FF80-\$FFF1	Device-specific interrupt sources (HCS12)

1. See SoC Guide and Interrupt Block Guide for further details
2. 16 bits Vector Address based
3. The Vector Base is a 16 bit address which is accumulated from :
  - a) A fixed value \$FF00 (HCS12)
  - b) Contents of Interrupt Vector Base Register (upper byte) and \$00 (lower byte) (HCS12X).

The CPU12 can handle up to 128 exception vectors, but the number actually used varies from device to device, and some vectors are reserved for Motorola use. Refer to SoC Guide for more information. The HCS12X devices typically allow the user to configure the start address of the vector table. Refer to the Interrupt Module Block Guide for further information.

Exceptions can be classified by the effect of the X and I interrupt mask bits on recognition of a pending request.

- Resets, the unimplemented opcode trap, and the SWI instruction are not affected by the X and I mask bits.
- Interrupt service requests from the  $\overline{XIRQ}$  pin are inhibited when  $X = 1$ , but are not affected by the I bit.
- All other interrupts are inhibited when  $I = 1$ .

### 7.3 Exception Priority

A hardware priority hierarchy determines which reset or interrupt is serviced first when simultaneous requests are made. Six sources are not maskable. The remaining sources are maskable, and the device integration module typically can change the relative priorities of

maskable interrupts. Refer to [7.5 Interrupts](#) for more detail concerning interrupt priority and servicing.

The priorities of the unmaskable sources are:

1. System Reset or power-on reset (POR)
2. Clock Monitor reset
3. Computer operating properly (COP) watchdog reset
4. Non-maskable interrupt request ( $\overline{XIRQ}$ ) signal
5. Unimplemented opcode trap
6. Software interrupt instruction (SWI)

System reset and POR share the highest exception-processing priority, followed by clock monitor reset, and then the on-chip watchdog reset.

The  $\overline{XIRQ}$  interrupt is pseudo-non-maskable. After reset, the X bit in the CCR is set, which inhibits all interrupt service requests from the  $\overline{XIRQ}$  pin until the X bit is cleared. The X bit can be cleared by a program instruction, but program instructions cannot change X from 0 to 1. Once the X bit is cleared, interrupt service requests made via the  $\overline{XIRQ}$  pin become non-maskable.

The unimplemented page 2 opcode trap (TRAP) and the SWI are special cases. In one sense, these two exceptions have very low priority, because any enabled interrupt source that is pending prior to the time exception processing begins will take precedence. However, once the CPU12 begins processing a TRAP or SWI, neither can be interrupted. Also, since these are mutually exclusive instructions, they have no relative priority.

All remaining interrupts are subject to masking via the I bit in the CCR. Most HCS12 microcontroller units (MCU) have an external  $\overline{IRQ}$  pin, which is assigned the highest I-bit interrupt priority and an internal periodic real-time interrupt generator, which has the next highest priority. The other maskable sources have default priorities that follow the address order of the interrupt vectors — the higher the address, the higher the priority of the interrupt. Other maskable interrupts are associated with on-chip peripherals such as timers or serial ports. Typically, logic in the device integration module can give one I-masked source priority over other I-masked sources. Refer to the documentation for the specific HCS12 derivative for more information.

## 7.4 Resets

HCS12 devices perform resets with a combination of hardware and software. Integration module circuitry determines the type of reset that has occurred, performs basic system configuration, then passes control to the CPU12. The CPU12 fetches a vector determined by the type of reset that has occurred, jumps to the address pointed to by the vector, and begins to execute code at that address.

There are four possible sources of reset are:

- System reset :
  - $\overline{\text{RESET}}$  pin
  - Power On reset (POR)
  - Low Voltage reset
  - Illegal address reset (S12X only)
- Clock monitor reset
- COP watchdog reset

Power-on reset (POR) and external reset share the same reset vector. The computer operating properly (COP) reset and the clock monitor reset each have a vector.

### 7.4.1 Power-On Reset

The HCS12 incorporate circuitry to detect a positive transition in the  $V_{DD}$  supply and initialize the device during cold starts, generally by asserting the reset signal internally. The signal is typically released after a delay that allows the device clock generator to stabilize.

### 7.4.2 External Reset

The MCU distinguishes between internal and external resets by sensing how quickly the signal on the  $\overline{\text{RESET}}$  pin rises to logic level 1 after it has been asserted. When the MCU senses any of the four reset conditions, internal circuitry drives the  $\overline{\text{RESET}}$  signal low for N clock cycles, then releases. M clock cycles later, the MCU samples the state of the signal applied to the  $\overline{\text{RESET}}$  pin. If the signal is still low, an external reset has occurred. If the signal is high, reset is assumed to have been initiated internally by either the COP system or the clock monitor.

### 7.4.3 COP Reset

The MCU includes a computer operating properly (COP) system to help protect against software failures. When the COP is enabled, software must write a particular code sequence to a specific address to keep a watchdog timer from timing out. If software fails to execute the sequence properly, a reset occurs.

### 7.4.4 Clock Monitor Reset

The clock monitor circuit uses an internal RC circuit to determine whether clock frequency is above a predetermined limit. If clock frequency falls below the limit when the clock monitor is enabled, a reset occurs.

## 7.5 Interrupts

Each HCS12 device can recognize a number of interrupt sources. Each source has a vector in the vector table. The  $\overline{\text{XIRQ}}$  signal, the unimplemented opcode trap, and the SWI instruction are non-maskable, and have a fixed priority. The remaining interrupt sources can be masked by the I bit. In most devices, the external interrupt request pin is assigned the highest maskable interrupt priority, and the internal periodic real-time interrupt generator has the next highest priority. Other maskable interrupts are associated with on-chip peripherals such as timers or serial ports. These maskable sources have default priorities that follow the address order of the interrupt vectors. The higher the vector address, the higher the priority of the interrupt. Typically, a device integration module incorporates logic that can give any one maskable source priority over other maskable sources.

### 7.5.1 Non-Maskable Interrupt Request ( $\overline{\text{XIRQ}}$ )

The  $\overline{\text{XIRQ}}$  input is an updated version of the non-maskable interrupt ( $\overline{\text{NMI}}$ ) input of earlier MCUs. The  $\overline{\text{XIRQ}}$  function is disabled during system reset and upon entering the interrupt service routine for an  $\overline{\text{XIRQ}}$  interrupt.

During reset, both the I bit and the X bit in the CCR are set. This disables maskable interrupts and interrupt service requests made by asserting the  $\overline{XIRQ}$  signal. After minimum system initialization, software can clear the X bit using an instruction such as `ANDCC #$BF`. Software cannot set the X bit from 0 to 1 once it has been cleared, and interrupt requests made via the  $\overline{XIRQ}$  pin become non-maskable. When a non-maskable interrupt is recognized, both the X and I bits are set after context is saved. The X bit is not affected by maskable interrupts. Execution of a return-from-interrupt (RTI) instruction at the end of the interrupt service routine normally restores the X and I bits to the pre-interrupt request state.

## 7.5.2 Maskable Interrupts

Maskable interrupt sources include on-chip peripheral systems and external interrupt service requests. Interrupts from these sources are recognized when the global interrupt mask bit (I) in the CCR is cleared. The default state of the I bit out of reset is 1, but it can be written at any time.

The interrupt module manages maskable interrupt priorities. Typically, an on-chip interrupt source is subject to masking by associated bits in control registers in addition to global masking by the I bit in the CCR. Sources generally must be enabled by writing one or more bits in associated control registers. There may be other interrupt-related control bits and flags, and there may be specific register read-write sequences associated with interrupt service. Refer to individual on-chip peripheral descriptions for details.

## 7.5.3 Interrupt Recognition

Once enabled, an interrupt request can be recognized at any time after the I mask bit is cleared. When an interrupt service request is recognized, the CPU12 responds at the completion of the instruction being executed. Interrupt latency varies according to the number of cycles required to complete the current instruction. Because the fuzzy logic rule evaluation (REV), fuzzy logic rule evaluation weighted (REWV), and weighted average (WAV) instructions can take many cycles to complete, they are designed so that they can be interrupted. Instruction execution resumes when interrupt execution is complete.

When the CPU12 begins to service an interrupt, the instruction queue is refilled, a return address is calculated, and then the return address and the contents of the CPU12 registers are stacked as shown in [Table 7-2](#) for HCS12 and as shown in [Table 7-3](#) for the HCS12X.

**Table 7-2. HCS12 Stacking Order on Entry to Interrupts**

Memory Location	CPU12 Registers
SP + 7	RTN <sub>H</sub> : RTN <sub>L</sub>
SP + 5	Y <sub>H</sub> : Y <sub>L</sub>
SP + 3	X <sub>H</sub> : X <sub>L</sub>
SP + 1	B : A
SP	CCR

**Table 7-3. HCS12X Stacking Order on Entry to Interrupts**

Memory Location	CPU12 Registers
SP + 8	RTN <sub>H</sub> : RTN <sub>L</sub>
SP + 6	Y <sub>H</sub> : Y <sub>L</sub>
SP + 4	X <sub>H</sub> : X <sub>L</sub>
SP + 2	B : A
SP	CCR <sub>H</sub> :CCR <sub>L</sub>

After the CCR is stacked, the I bit (and the X bit, if an  $\overline{XIRQ}$  interrupt service request caused the interrupt) is set to prevent other interrupts from disrupting the interrupt service routine. Execution continues at the address pointed to by the vector for the highest-priority interrupt that was pending at the beginning of the interrupt sequence. At the end of the interrupt service routine, an RTI instruction restores context from the stacked registers, and normal program execution resumes.

## 7.5.4 External Interrupts

External interrupt service requests are made by asserting an active-low signal connected to the  $\overline{IRQ}$  pin. Typically, control bits affect how the signal is detected and recognized.

The I bit serves as the  $\overline{\text{IRQ}}$  interrupt enable flag. When an  $\overline{\text{IRQ}}$  interrupt is recognized, the I bit is set to inhibit interrupts during the interrupt service routine. Before other maskable interrupt requests can be recognized, the I bit must be cleared. This is generally done by an RTI instruction at the end of the service routine.

### 7.5.5 Return-from-Interrupt Instruction (RTI)

RTI is used to terminate interrupt service routines. RTI is an 8-cycle instruction when no other interrupt is pending and 11 cycles, when another interrupt is pending. In either case, the first five cycles are used to restore (pull) the CCR, B:A, X, Y, and the return address from the stack. If no other interrupt is pending at this point, three program words are fetched to refill the instruction queue from the area of the return address and processing proceeds from there.

If another interrupt is pending after registers are restored, a new vector is fetched, and the stack pointer is adjusted to point at the CCR value that was just recovered ( $\text{SP} = \text{SP} - 9$  for HCS12 and  $\text{SP} = \text{SP} - 10$  for HCS12X). This makes it appear that the registers have been stacked again. After the SP is adjusted, three program words are fetched to refill the instruction queue, starting at the address the vector points to. Processing then continues with execution of the instruction that is now at the head of the queue.

## 7.6 Unimplemented Opcode Trap

The HCS12 has opcodes in all 256 positions in the page 1 opcode map, but only 54 of the 256 positions on page 2 of the opcode map are used. If the CPU12 attempts to execute one of the 202 unused opcodes on page 2, an unimplemented opcode trap occurs. The 202 unimplemented opcodes are essentially interrupts that share a common interrupt vector, \$FFF8:\$FFF9.

The HCS12X has opcodes in all 256 positions in the page 1 opcode map, and 227 of the 256 positions on page 2 of the opcode map are used. If the CPU12 attempts to execute one of the 29 unused opcodes on page 2, an unimplemented opcode trap occurs. The 29 unimplemented opcodes are essentially interrupts that share a common interrupt vector, \$FFF8:\$FFF9.

The CPU12 uses the next address after an unimplemented page 2 opcode as a return address. In the CPU12, the stacked return address can be used to calculate the address of the unimplemented opcode for software-controlled traps.

### 7.7 Software Interrupt Instruction (SWI)

Execution of the SWI instruction causes an interrupt without an interrupt service request. SWI is not inhibited by the global mask bits in the CCR, and execution of SWI sets the I mask bit. Once an SWI interrupt begins, maskable interrupts are inhibited until the I bit in the CCR is cleared. This typically occurs when an RTI instruction at the end of the SWI service routine restores context.

### 7.8 Exception Processing Flow

The first cycle in the exception processing flow for all CPU12 exceptions is the same, regardless of the source of the exception. Between the first and second cycles of execution, the CPU12 chooses one of three alternative paths. The first path is for resets, the second path is for pending X or I interrupts, and the third path is used for software interrupts (SWI) and trapping unimplemented opcodes. The last two paths are virtually identical, differing only in the details of calculating the return address. Refer to [Figure 7-1](#) for the following discussion.

#### 7.8.1 Vector Fetch

The first cycle of all exception processing, regardless of the cause, is a vector fetch. The vector points to the address where exception processing will continue. Exception vectors are stored in a table located at the top of the memory map (\$FFxx) if not placed elsewhere using the Interrupt Vector Base Register (HCS12X only). The CPU12 cannot use the fetched vector until the third cycle of the exception processing sequence.

During the vector fetch cycle, the CPU12 issues a signal that tells the interrupt module to drive the vector address of the highest priority,

pending exception onto the system address bus (the CPU12 does not provide this address).

After the vector fetch, the CPU12 selects one of the three alternate execution paths, depending upon the cause of the exception.

### **7.8.2 Reset Exception Processing**

If reset caused the exception, processing continues to cycle 2.0. This cycle sets the S, X, and I bits in the CCR. Cycles 3.0 through 5.0 are program word fetches that refill the instruction queue. Fetches start at the address pointed to by the reset vector. When the fetches are completed, exception processing ends, and the CPU12 starts executing the instruction at the head of the instruction queue.

# Exception Processing

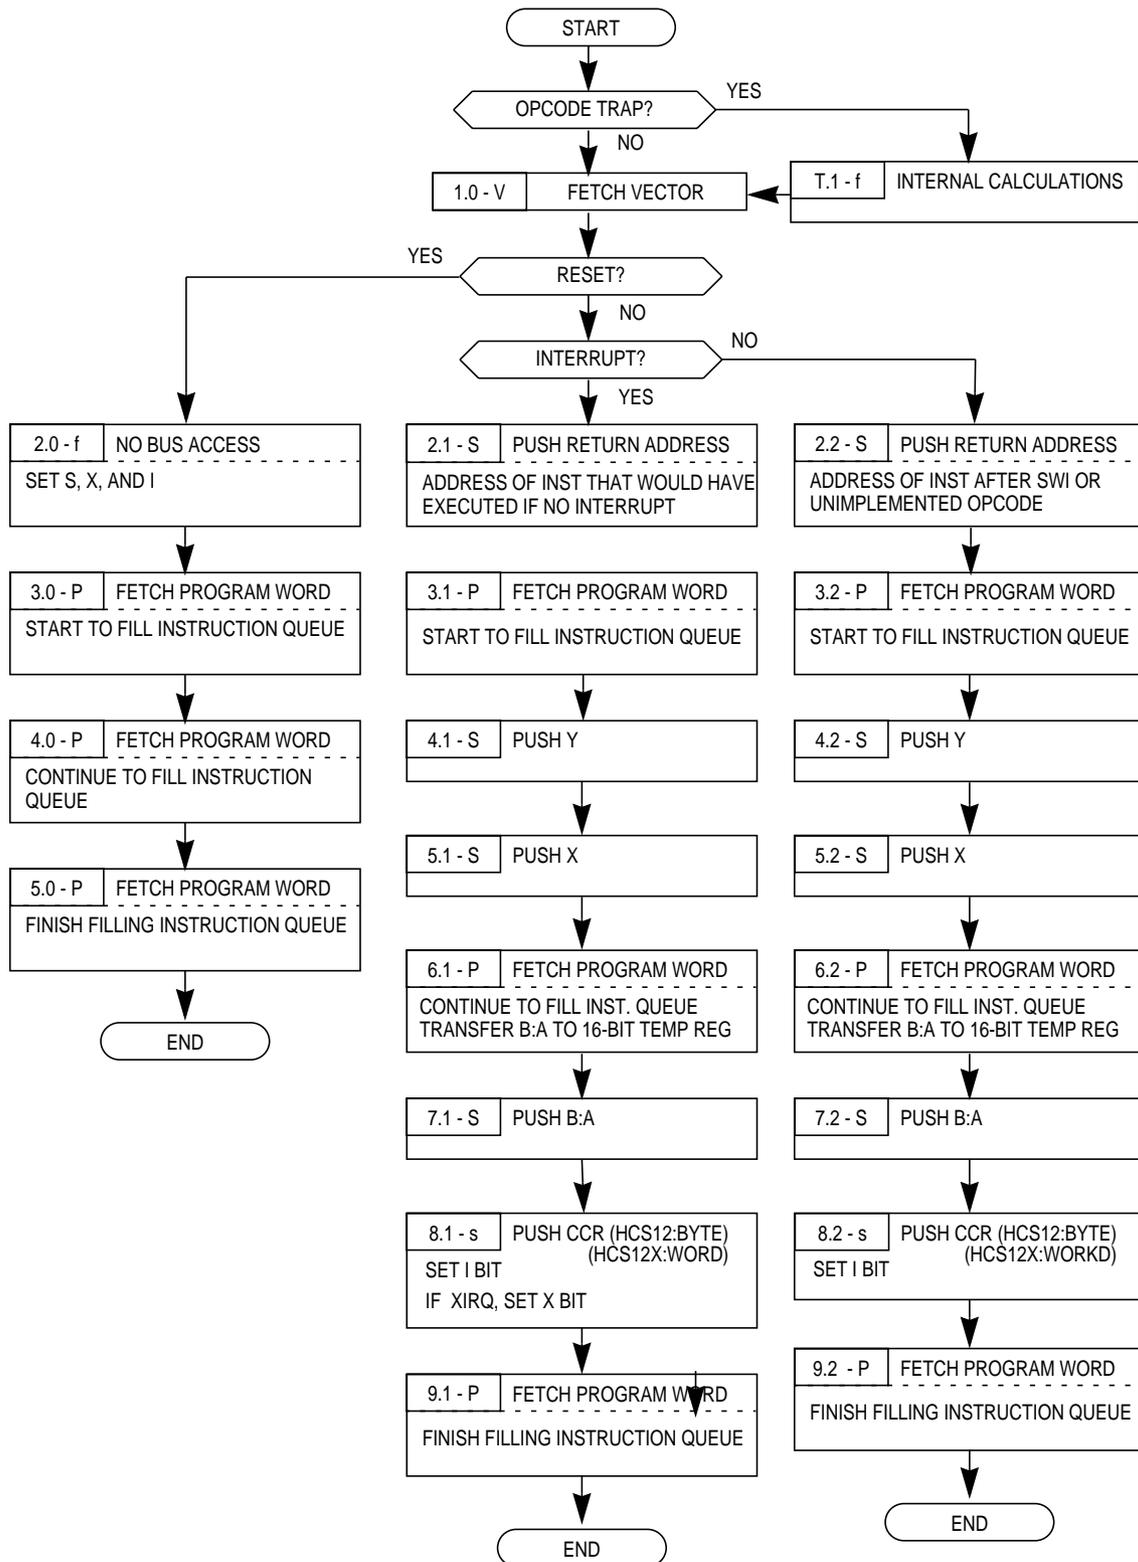

Figure 7-1. Exception Processing Flow Diagram

### 7.8.3 Interrupt and Unimplemented Opcode Trap Exception Processing

If an exception was not caused by a reset, a return address is calculated.

- Cycles 2.1 and 2.2 are both S cycles (stack a 16-bit word), but the CPU12 performs different return address calculations for each type of exception.
  - When an X- or I-related interrupt causes the exception, the return address points to the next instruction that would have been executed had processing not been interrupted.
  - When an exception is caused by an SWI opcode or by an unimplemented opcode (see [7.6 Unimplemented Opcode Trap](#)), the return address points to the next address after the opcode.
- Once calculated, the return address is pushed onto the stack.
- Cycles 3.1 through 9.1 are identical to cycles 3.2 through 9.2 for the rest of the sequence, except for optional setting of the X mask bit performed in cycle 8.1 (see below).
- Cycle 3.1/3.2 is the first of three program word fetches that refill the instruction queue.
- Cycle 4.1/4.2 pushes Y onto the stack.
- Cycle 5.1/5.2 pushes X onto the stack.
- Cycle 6.1/6.2 is the second of three program word fetches that refill the instruction queue. During this cycle, the contents of the A and B accumulators are concatenated into a 16-bit word in the order B:A.
- Cycle 7.1/7.2 pushes the 16-bit word containing B:A onto the stack.
- Cycle 8.1/8.2 pushes the 8-bit CCR (HCS12) respectively a 16-bit CCRW (HCS12X) onto the stack, then updates the mask bits.
  - When an  $\overline{XIRQ}$  interrupt causes an exception, both X and I are set, which inhibits further interrupts during exception processing.
  - When any other interrupt causes an exception, the I bit is set, but the X bit is not changed.

- Cycle 9.1/9.2 is the third of three program word fetches that refill the instruction queue. It is the last cycle of exception processing. After this cycle the CPU12 starts executing the first cycle of the instruction at the head of the instruction queue.

## Section 8. Instruction Queue

### 8.1 Introduction

This section describes development and debug support features related to the central processor unit (CPU12). Topics include:

- Instruction queue operation and reconstruction
- Instruction tagging

### 8.2 External Reconstruction of the Queue

The CPU12 uses an instruction queue to buffer program information and increase instruction throughput.. The HCS12 queue consists of three 16-bit stages. Program information is always fetched in aligned 16-bit words. At least three bytes of program information are available to the CPU12 when instruction execution begins.

Because of the queue, program information is fetched a few cycles before it is used by the CPU12. Internally, the microcontroller unit (MCU) only needs to buffer the fetched data. But, in order to monitor cycle-by-cycle CPU12 activity externally, it is necessary to capture data and address to discern what is happening in the instruction queue.

External pins, (IPIPE[1:0] for HCS12), (IQSTAT[3:0] for HCS12X), provide information about data movement in the queue and instruction execution. The instruction queue and cycle-by-cycle activity can be reconstructed in real time or from trace history captured by a logic analyzer. However, neither scheme can be used to stop the CPU12 at a specific instruction. By the time an operation is visible outside the MCU, the instruction has already begun execution. A separate instruction tagging mechanism is provided for this purpose. A tag follows the information in the queue as the queue is advanced. During debugging, the CPU12 enters active background debug mode when a tagged instruction reaches the head of the queue, rather than executing the

tagged instruction. For more information about tagging, refer to [8.5 Instruction Tagging \(HCS12\)](#).

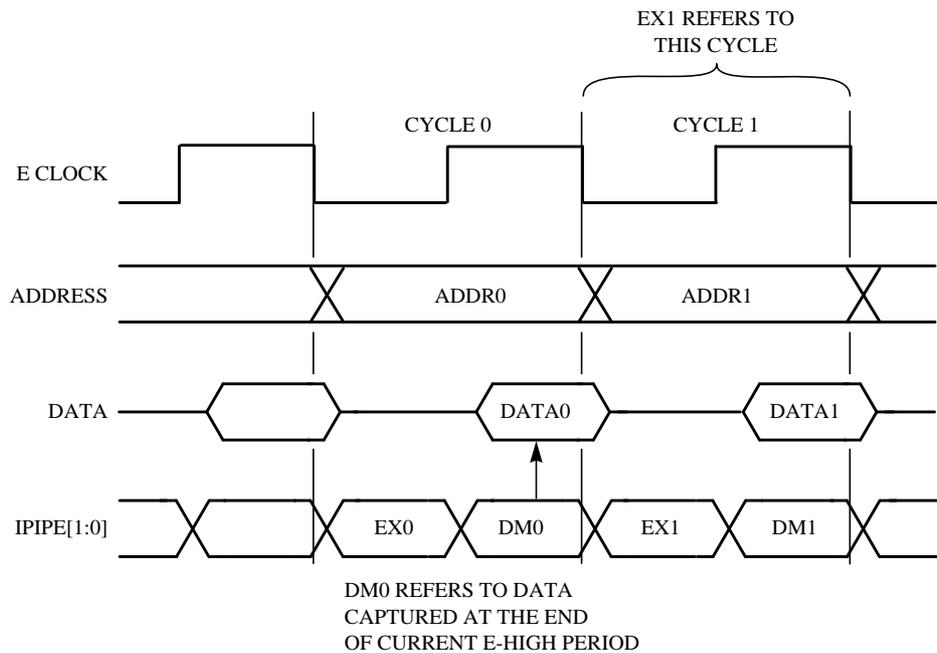

### 8.3 Instruction Queue Status Signals

The (IPIPE1:0] for HCS12), (IQSTAT[3:0] for HCS12X) signals carry information about data movement and instruction execution during normal CPU12 operation.

To reconstruct the queue, the information carried by the status signals must be captured externally. The definition of the this signals is different from HCS12 and HCS12X, refer to [8.3.1 HCS12 Timing Detail](#) and [8.3.2 HCS12X Timing Detail](#)

### 8.3.1 HCS12 Timing Detail

In the HCS12, data-movement information is available when E clock is high or on falling edges of the E clock; execution-start information is available when E clock is low or on rising edges of the E clock, as shown in **Figure 8-1**. Data-movement information refers to data on the bus. Execution-start information refers to the bus cycle that starts with that E-low time and continues through the following E-high time. **Table 8-1** summarizes the information encoded on the IPIPE1 and IPIPE0 pins.

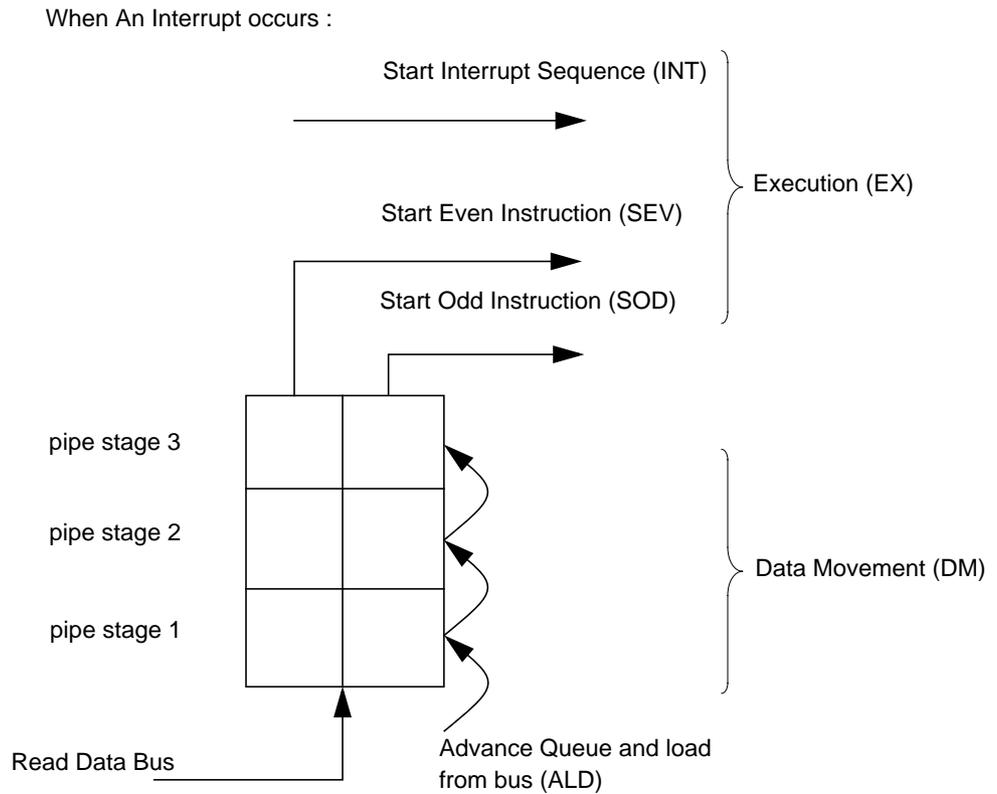

**Figure 8-1. Queue Status Signal Timing (HCS12)**

**Table 8-1. IPIPE1 and IPIPE0 Decoding HCS12**

	Mnemonic	Meaning
<b>Data Movement</b>	<b>Capture at E Fall in HCS12</b>	
0:0	—	No movement
0:1	—	Unused?
1:0	ALD	Advance queue and load from bus
1:1		
<b>Execution Start</b>	<b>Capture at E Rise in HCS12</b>	
0:0	—	No start
0:1	INT	Start interrupt sequence
1:0	SEV	Start even instruction
1:1	SOD	Start odd instruction

### 8.3.2 HCS12X Timing Detail

In the HCS12X, data-movement information and execution-start information as shown in **Figure 8-2** are demultiplexed and available on the signal IQSTAT[3:0] when the next E clock is low, as shown in **Figure 8-3**. Data-movement information refers to data on the previous two bus cycles. Execution-start information refers to the previous bus cycle. **Table 8-2** summarizes the information on the IQSTAT[3:0].

**Figure 8-2. Pipe Status Signal**

IQSTAT contains Data movement of the pipe in time T-2 (ALD) and/or the corresponding execution information in T-1 (INT, SEV or SOD)

**Figure 8-3 IQSTAT Timing**

### 8.3.3 Null

The (00 for HCS12) (0000 for HCS12X) data movement state indicates that there was no data movement in the instruction queue; the (00 for HCS12) (0000 for HCS12X) execution start state indicates continuation of an instruction or interrupt sequence (no new instruction or interrupt start).

### 8.3.4 ALD — Advance and Load from Data Bus

The instruction queue is advanced by one word and stage one is refilled with a word of program information from the data bus. The CPU12 requested the information two bus cycles earlier but, due to access delays, the information was not available until the E cycle referred to by the ALD code.

### 8.3.5 INT — Interrupt Sequence Start

The E cycle associated with this code is the first cycle after an interrupt sequence. Normally, this cycle is one cycle after a read of the interrupt

vector. However, in systems that have interrupt vectors in external memory and an 8-bit data bus, the cycle before this code reads the upper byte of the 16-bit interrupt vector.

**Table 8-2. IQSTAT[3:0] on HCS12X**

	<b>Mnemonic</b>	<b>Meaning</b>
<b>Execution Start</b>	<b>Capture at E Fall in HCS12X</b>	
0001	INT	Start interrupt sequence
0010	SOD	Start instruction at odd address
0100	SEV	Start instruction at even address
<b>Data Movement</b>	<b>Capture at E Fall in HCS12X</b>	
1000	ALD	Advance the instruction queue and load first stage
<b>Data Movement &amp; Execution Start</b>	<b>Capture at E Fall in HCS12X</b>	
0000	Null	No movement, No start
1100	ALD&SEV	Advance the instruction queue and load first stage then Start instruction at even address
1010	ALD&SOD	Advance the instruction queue and load first stage then Start instruction at odd address
1001	ALD&INT	Advance the instruction queue and load first stage then Start interrupt sequence
Others	Not Implemented	---

### 8.3.6 SEV — Start Instruction on Even Address

The E cycle associated with this code is the first cycle after the instruction in the even (high order) half of the word at the head of the instruction queue. The queue treats the \$18 prebyte for instructions on page 2 of the opcode map as a special 1-byte, 1-cycle instruction, except that interrupts are not recognized at the boundary between the prebyte and the rest of the instruction.

## 8.3.7 SOD — Start Instruction on Odd Address

The E cycle associated with this code is the first cycle after the instruction in the odd (low order) half of the word at the head of the instruction queue. The queue treats the \$18 prebyte for instructions on page 2 of the opcode map as a special 1-byte, 1-cycle instruction, except that interrupts are not recognized at the boundary between the prebyte and the rest of the instruction.

## 8.4 Queue Reconstruction (for HCS12)

The raw signals required for queue reconstruction are the address bus (ADDR), the data bus (DATA), the system clock (E), and the queue status signals (IPIPE1 and IPIPE2). An ALD data movement implies a read; therefore, it is not necessary to capture the  $R/\overline{W}$  signal. An E clock cycle begins at a falling edge of E. Addresses and execution status must be captured at the rising E edge in the middle of the cycle. Data and data-movement status must be captured at the falling edge of E at the end of the cycle. These captures can then be organized into records with one record per E clock cycle.

Implementation details depend on the type of MCU and the mode of operation. For instance, the data bus can be eight bits or 16 bits wide, and nonmultiplexed or multiplexed. In all cases, the externally reconstructed queue must use 16-bit words. Demultiplexing and assembly of 8-bit data into 16-bit words is done before program information enters the real queue, so it must also be done for the external reconstruction.

An example:

Systems with an 8-bit data bus and a program stored in external memory require two cycles for each program word fetch. MCU bus-control logic freezes the CPU12 clocks long enough to do two 8-bit accesses rather than a single 16-bit access, so the CPU12 sees only 16-bit words of program information. To recover the 16-bit program words externally, latch the data bus state at the falling edge of E when ADDR0 = 0, and gate the outputs of the latch onto DATA[15:8] when an ALD cycle occurs. Since the 8-bit data bus is connected to DATA[7:0], the 16-bit word on the data lines corresponds to the ALD during the last half of the second 8-bit fetch,

which is always to an odd address. IPIPE[1:0] status signals indicate 0:0 for the second half of the E cycle corresponding to the first 8-bit fetch.

Some MCUs have address lines to support memory expansion beyond the standard 64-Kbyte address space. When memory expansion is used, expanded addresses must also be captured and maintained.

### 8.4.1 Queue Reconstruction Registers (for HCS12)

Queue reconstruction requires the following registers, which can be implemented as software variables when previously captured trace data is used, or as hardware latches in real time.

#### 8.4.1.1 *fetch\_add* Register

This register buffers the fetch address.

#### 8.4.1.2 *st1\_add, st1\_dat* Registers

These registers contain address and data for the first stage of the reconstructed instruction queue.

#### 8.4.1.3 *st2\_add, st2\_dat* Registers

These registers contain address and data for the middle stage of the reconstructed instruction queue.

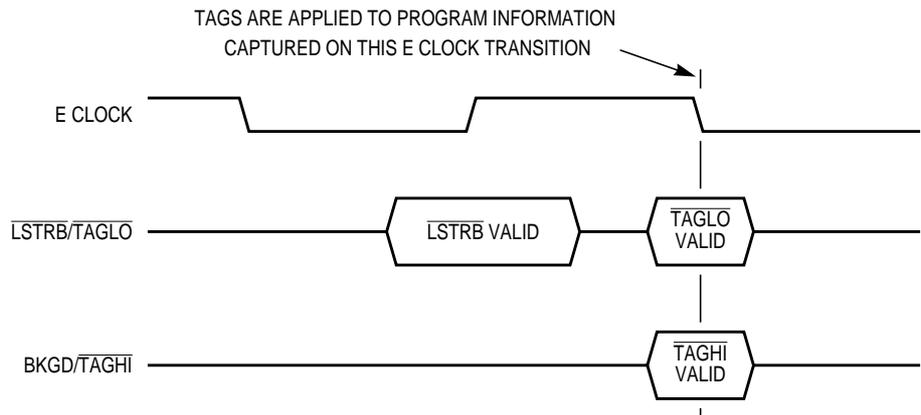

#### 8.4.1.4 *st3\_add, st3\_dat* Registers

These registers contain address and data for the final stage of the reconstructed instruction queue. When the IPIPE[1:0] signals indicate the execution status, the address and opcode can be found in these registers.

## 8.5 Instruction Tagging (HCS12)

The instruction queue and cycle-by-cycle CPU12 activity can be reconstructed in real time or from trace history that was captured by a logic analyzer. However, the reconstructed queue cannot be used to stop the CPU12 at a specific instruction, because execution has already begun by the time an operation is visible outside the MCU. A separate instruction tagging mechanism is provided for this purpose.

Executing the BDM TAGGO command configures two MCU pins for tagging. The  $\overline{\text{TAGLO}}$  signal shares a pin with the  $\overline{\text{LSTRB}}$  signal, and the  $\overline{\text{TAGHI}}$  signal shares the BKGD pin. Tagging information is latched on the falling edge of ECLK, as shown in [Figure 8-4](#).

**Figure 8-4. Tag Input Timing (HCS12)**

[Table 8-3](#) shows the functions of the two independent tagging pins. The presence of logic level 0 on either pin at the fall of ECLK tags (marks) the associated byte of program information as it is read into the instruction queue. Tagging is allowed in all modes. Tagging is disabled when BDM becomes active.

**Table 8-3. Tag Pin Function (HCS12)**

$\overline{\text{TAGHI}}$	$\overline{\text{TAGLO}}$	Tag
1	1	No tag
1	0	Low byte
0	1	High byte
0	0	Both bytes

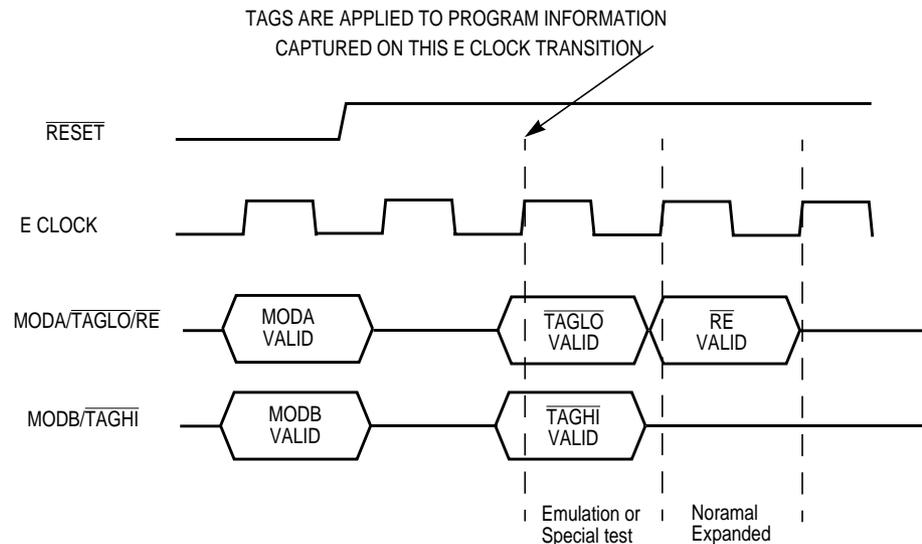

In HCS12 and M68HC12 derivatives that have hardware breakpoint capability, the breakpoint control logic and BDM control logic use the same internal signals for instruction tagging. The CPU12 does not differentiate between the two kinds of tags.

The tag follows program information as it advances through the queue. When a tagged instruction reaches the head of the queue, the CPU12 enters active background debug mode rather than executing the instruction.

## 8.6 Instruction Tagging (HCS12X)

The instruction queue and cycle-by-cycle CPU12 activity can be reconstructed in real time or from trace history that was captured by a logic analyzer. However, the reconstructed queue cannot be used to stop the CPU12 at a specific instruction, because execution has already begun by the time an operation is visible outside the MCU. A separate instruction tagging mechanism is provided for this purpose.

The  $\overline{\text{TAGLO}}$  signal shares a pin with the  $\overline{\text{RE}}$  and  $\text{MODA}$  signals, and the  $\overline{\text{TAGHI}}$  signal shares the  $\text{MODB}$  pin. Tagging information is latched on the rising edge of  $\text{ECLK}$ , as shown in [Figure 8-5](#).

**Figure 8-5. Tag Input Timing (HCS12X)**

[Table 8-4](#) shows the functions of the two independent tagging pins. The presence of logic level 0 on either pin at the rise of  $\text{ECLK}$  tags (marks) the associated byte of program information as it is read into the instruction queue. Tagging is allowed only in emulation modes. Tagging is disabled when BDM becomes active.

**Table 8-4. Tag Pin Function (HCS12X)**

$\overline{\text{TAGHI}}$	$\overline{\text{TAGLO}}$	Tag
1	1	No tag
1	0	Low byte

**Table 8-4. Tag Pin Function (HCS12X)**

<b>TAGHI</b>	<b>TAGLO</b>	<b>Tag</b>
0	1	High byte
0	0	Both bytes

On the HCS12X internal breakpoints can also be generated by the S12XDBG module. Breakpoints generated by the TAGLO or TAGHI have a higher priority than the internally generated breakpoints.

The tag follows program information as it advances through the queue. When a tagged instruction reaches the head of the queue, a taghit occurs generating a hardware breakpoint to BDM or SWI.

## Section 9. Fuzzy Logic Support

### 9.1 Introduction

The instruction set of the central processor unit (CPU12) is the first instruction set to specifically address the needs of fuzzy logic. This section describes the use of fuzzy logic in control systems, discusses the CPU12 fuzzy logic instructions, and provides examples of fuzzy logic programs.

The CPU12 includes four instructions that perform specific fuzzy logic tasks. In addition, several other instructions are especially useful in fuzzy logic programs. The overall C-friendliness of the instruction set also aids development of efficient fuzzy logic programs.

This section explains the basic fuzzy logic algorithm for which the four fuzzy logic instructions are intended. Each of the fuzzy logic instructions are then explained in detail. Finally, other custom fuzzy logic algorithms are discussed, with emphasis on use of other CPU12 instructions.

The four fuzzy logic instructions are:

- MEM (determine grade of membership), which evaluates trapezoidal membership functions
- REV (fuzzy logic rule evaluation) and REVW (fuzzy logic rule evaluation weighted), which perform unweighted or weighted MIN-MAX rule evaluation
- WAV (weighted average), which performs weighted average defuzzification on singleton output membership functions.

Other instructions that are useful for custom fuzzy logic programs include:

- MINA (place smaller of two unsigned 8-bit values in accumulator A)
- EMIND (place smaller of two unsigned 16-bit values in accumulator D)
- MAXM (place larger of two unsigned 8-bit values in memory)

- EMAXM (place larger of two unsigned 16-bit values in memory)
- TBL (table lookup and interpolate)
- ETBL (extended table lookup and interpolate)
- EMACS (extended multiply and accumulate signed 16-bit by 16-bit to 32-bit)

For higher resolution fuzzy programs, the fast extended precision math instructions in the CPU12 are also beneficial. Flexible indexed addressing modes help simplify access to fuzzy logic data structures stored as lists or tabular data structures in memory.

The actual logic additions required to implement fuzzy logic support in the CPU12 are quite small, so there is no appreciable increase in cost for the typical user. A fuzzy inference kernel for the CPU12 requires one-fifth as much code space and executes almost 50 times faster than a comparable kernel implemented on a typical midrange microcontroller. By incorporating fuzzy logic support into a high-volume, general-purpose microcontroller product family, Motorola has made fuzzy logic available for a huge base of applications.

## 9.2 Fuzzy Logic Basics

This is an overview of basic fuzzy logic concepts. It can serve as a general introduction to the subject, but that is not the main purpose. There are a number of fuzzy logic programming strategies. This discussion concentrates on the methods implemented in the CPU12 fuzzy logic instructions. The primary goal is to provide a background for a detailed explanation of the CPU12 fuzzy logic instructions.

In general, fuzzy logic provides for set definitions that have fuzzy boundaries rather than the crisp boundaries of Aristotelian logic. These sets can overlap so that, for a specific input value, one or more sets associated with linguistic labels may be true to a degree at the same time. As the input varies from the range of one set into the range of an adjacent set, the first set becomes progressively less true while the second set becomes progressively more true.

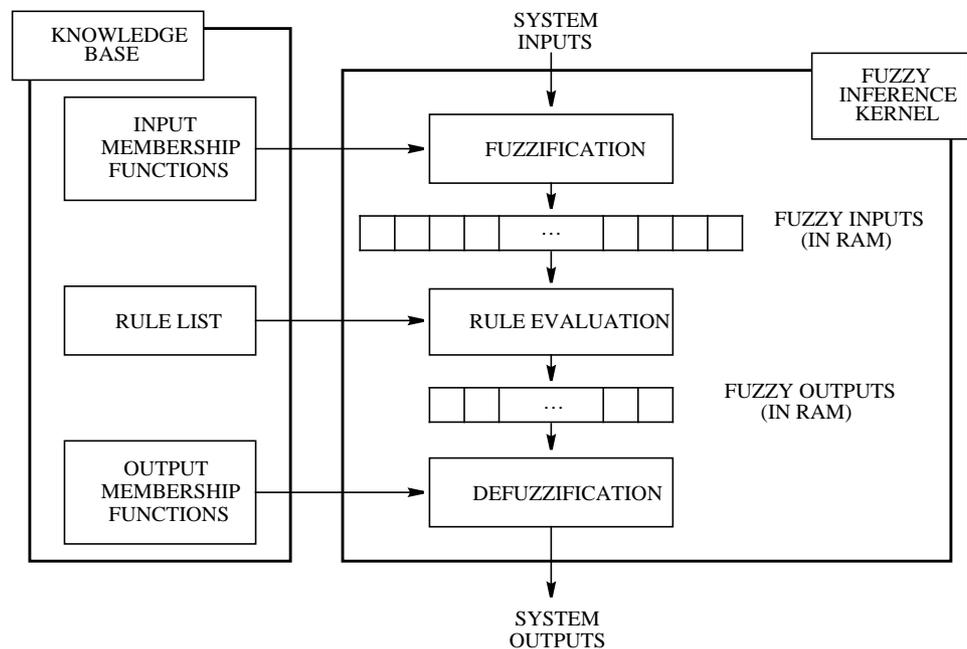

Fuzzy logic has membership functions which emulate human concepts like “temperature is warm”; that is, conditions are perceived to have gradual boundaries. This concept seems to be a key element of the human ability to solve certain types of complex problems that have eluded traditional control methods.

Fuzzy sets provide a means of using linguistic expressions like “temperature is warm” in rules which can then be evaluated with a high degree of numerical precision and repeatability. This directly contradicts the common misperception that fuzzy logic produces approximate results — a specific set of input conditions always produces the same result, just as a conventional control system does.

A microcontroller-based fuzzy logic control system has two parts:

- A fuzzy inference kernel which is executed periodically to determine system outputs based on current system inputs
- A knowledge base which contains membership functions and rules

**Figure 9-1** is a block diagram of this kind of fuzzy logic system.

**Figure 9-1. Block Diagram of a Fuzzy Logic System**

The knowledge base can be developed by an application expert without any microcontroller programming experience. Membership functions are simply expressions of the expert’s understanding of the linguistic terms that describe the system to be controlled. Rules are ordinary language

statements that describe the actions a human expert would take to solve the application problem.

Rules and membership functions can be reduced to relatively simple data structures (the knowledge base) stored in non-volatile memory. A fuzzy inference kernel can be written by a programmer who does not know how the application system works. The only thing the programmer needs to do with knowledge base information is store it in the memory locations used by the kernel.

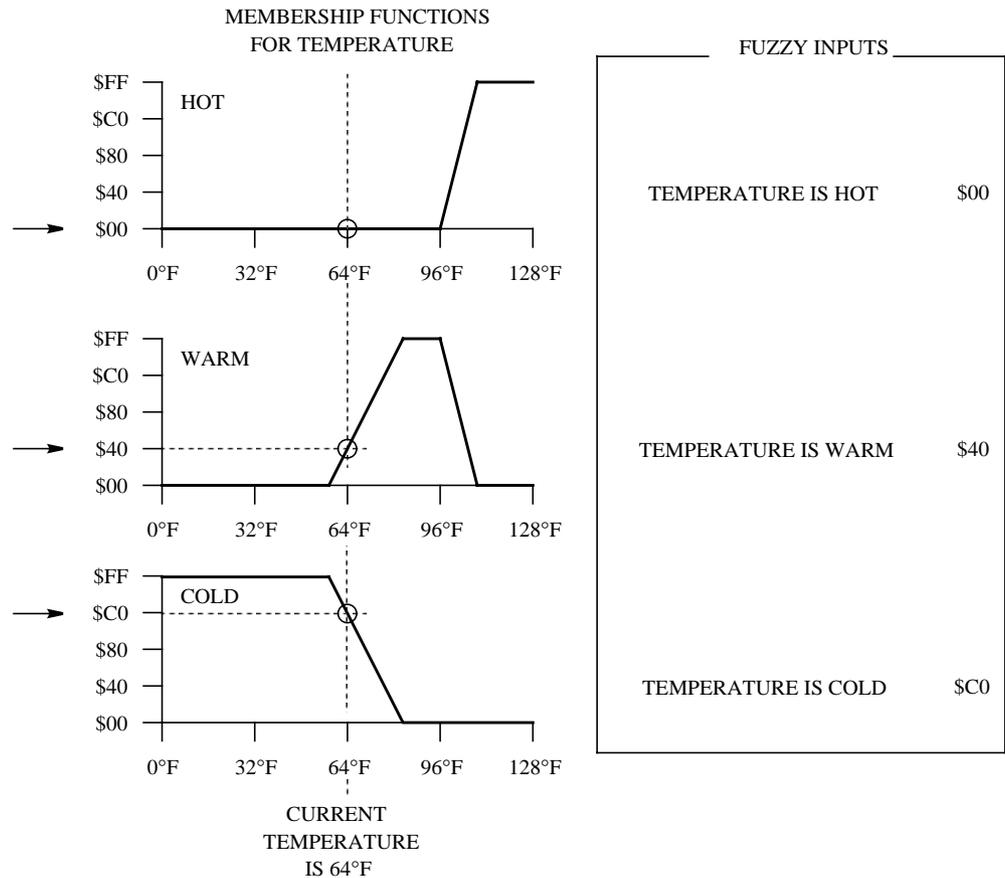

One execution pass through the fuzzy inference kernel generates system output signals in response to current input conditions. The kernel is executed as often as needed to maintain control. If the kernel is executed more often than needed, processor bandwidth and power are wasted; delaying too long between passes can cause the system to get too far out of control. Choosing a periodic rate for a fuzzy control system is the same as it would be for a conventional control system.

### 9.2.1 Fuzzification (MEM)

During the fuzzification step, the current system input values are compared against stored input membership functions to determine the degree to which each label of each system input is true. This is accomplished by finding the y-value for the current input value on a trapezoidal membership function for each label of each system input. The MEM instruction in the CPU12 performs this calculation for one label of one system input. To perform the complete fuzzification task for a system, several MEM instructions must be executed, usually in a program loop structure.

**Figure 9-2** shows a system of three input membership functions, one for each label of the system input. The x-axis of all three membership functions represents the range of possible values of the system input. The vertical line through all three membership functions represents a specific system input value. The y-axis represents degree of truth and varies from completely false (\$00 or 0 percent) to completely true (\$FF or 100 percent). The y-value where the vertical line intersects each of the membership functions, is the degree to which the current input value matches the associated label for this system input. For example, the expression “temperature is warm” is 25 percent true (\$40). The value \$40 is stored to a random-access memory (RAM) location and is called

a fuzzy input (in this case, the fuzzy input for “temperature is warm”). There is a RAM location for each fuzzy input (for each label of each system input).

**Figure 9-2. Fuzzification Using Membership Functions**

When the fuzzification step begins, the current value of the system input is in an accumulator of the CPU12, one index register points to the first membership function definition in the knowledge base, and a second index register points to the first fuzzy input in RAM. As each fuzzy input is calculated by executing a MEM instruction, the result is stored to the fuzzy input and both pointers are updated automatically to point to the locations associated with the next fuzzy input. The MEM instruction takes care of everything except counting the number of labels per system input and loading the current value of any subsequent system inputs.

The end result of the fuzzification step is a table of fuzzy inputs representing current system conditions.

### 9.2.2 Rule Evaluation (REV and REVW)

Rule evaluation is the central element of a fuzzy logic inference program. This step processes a list of rules from the knowledge base using current fuzzy input values from RAM to produce a list of fuzzy outputs in RAM. These fuzzy outputs can be thought of as raw suggestions for what the system output should be in response to the current input conditions. Before the results can be applied, the fuzzy outputs must be further processed, or defuzzified, to produce a single output value that represents the combined effect of all of the fuzzy outputs.

The CPU12 offers two variations of rule evaluation instructions. The REV instruction provides for unweighted rules (all rules are considered to be equally important). The REVW instruction is similar but allows each rule to have a separate weighting factor which is stored in a separate parallel data structure in the knowledge base. In addition to the weights, the two rule evaluation instructions also differ in the way rules are encoded into the knowledge base.

An understanding of the structure and syntax of rules is needed to understand how a microcontroller performs the rule evaluation task. An example of a typical rule is:

If temperature is warm and pressure is high, then heat is  
(should be) off.

At first glance, it seems that encoding this rule in a compact form understandable to the microcontroller would be difficult, but it is actually simple to reduce the rule to a small list of memory pointers. The antecedent portion of the rule is a statement of input conditions and the consequent portion of the rule is a statement of output actions.

The antecedent portion of a rule is made up of one or more (in this case two) antecedents connected by a fuzzy *and* operator. Each antecedent expression consists of the name of a system input, followed by *is*, followed by a label name. The label must be defined by a membership function in the knowledge base. Each antecedent expression corresponds to one of the fuzzy inputs in RAM. Since *and* is the only operator allowed to connect antecedent expressions, there is no need to

include these in the encoded rule. The antecedents can be encoded as a simple list of pointers to (or addresses of) the fuzzy inputs to which they refer.

The consequent portion of a rule is made up of one or more (in this case one) consequents. Each consequent expression consists of the name of a system output, followed by *is*, followed by a label name. Each consequent expression corresponds to a specific fuzzy output in RAM. Consequents for a rule can be encoded as a simple list of pointers to (or addresses of) the fuzzy outputs to which they refer.

The complete rules are stored in the knowledge base as a list of pointers or addresses of fuzzy inputs and fuzzy outputs. For the rule evaluation logic to work, there must be some means of knowing which pointers refer to fuzzy inputs and which refer to fuzzy outputs. There also must be a way to know when the last rule in the system has been reached.

- One method of organization is to have a fixed number of rules with a specific number of antecedents and consequents.
- A second method, employed in Motorola Freeware M68HC11 kernels, is to mark the end of the rule list with a reserved value, and use a bit in the pointers to distinguish antecedents from consequents.
- A third method of organization, used in the CPU12, is to mark the end of the rule list with a reserved value, and separate antecedents and consequents with another reserved value. This permits any number of rules, and allows each rule to have any number of antecedents and consequents, subject to the limits imposed by availability of system memory.

Each rule is evaluated sequentially, but the rules as a group are treated as if they were all evaluated simultaneously. Two mathematical operations take place during rule evaluation. The fuzzy *and* operator corresponds to the mathematical minimum operation and the fuzzy *or* operation corresponds to the mathematical maximum operation. The fuzzy *and* is used to connect antecedents within a rule. The fuzzy *or* is implied between successive rules. Before evaluating any rules, all fuzzy outputs are set to zero (meaning not true at all). As each rule is evaluated, the smallest (minimum) antecedent is taken to be the overall truth of the rule. This rule truth value is applied to each consequent of the rule (by storing this value to the corresponding fuzzy output) unless

the fuzzy output is already larger (maximum). If two rules affect the same fuzzy output, the rule that is most true governs the value in the fuzzy output because the rules are connected by an implied fuzzy *or*.

In the case of rule weighting, the truth value for a rule is determined as usual by finding the smallest rule antecedent. Before applying this truth value to the consequents for the rule, the value is multiplied by a fraction from zero (rule disabled) to one (rule fully enabled). The resulting modified truth value is then applied to the fuzzy outputs.

The end result of the rule evaluation step is a table of suggested or “raw” fuzzy outputs in RAM. These values were obtained by plugging current conditions (fuzzy input values) into the system rules in the knowledge base. The raw results cannot be supplied directly to the system outputs because they may be ambiguous. For instance, one raw output can indicate that the system output should be medium with a degree of truth of 50 percent while, at the same time, another indicates that the system output should be low with a degree of truth of 25 percent. The defuzzification step resolves these ambiguities.

### 9.2.3 Defuzzification (WAV)

The final step in the fuzzy logic program combines the raw fuzzy outputs into a composite system output. Unlike the trapezoidal shapes used for inputs, the CPU12 typically uses singletons for output membership functions. As with the inputs, the x-axis represents the range of possible values for a system output. Singleton membership functions consist of the x-axis position for a label of the system output. Fuzzy outputs correspond to the y-axis height of the corresponding output membership function.

The WAV instruction calculates the numerator and denominator sums for weighted average of the fuzzy outputs according to the formula:

$$\text{System Output} = \frac{\sum_{i=1}^n S_i F_i}{\sum_{i=1}^n F_i}$$

Where  $n$  is the number of labels of a system output,  $S_i$  are the singleton positions from the knowledge base, and  $F_i$  are fuzzy outputs from RAM.

For a common fuzzy logic program on the CPU12,  $n$  is eight or less (though this instruction can handle any value to 255) and  $S_i$  and  $F_i$  are 8-bit values. The final divide is performed with a separate EDIV instruction placed immediately after the WAV instruction.

Before executing WAV, an accumulator must be loaded with the number of iterations ( $n$ ), one index register must be pointed at the list of singleton positions in the knowledge base, and a second index register must be pointed at the list of fuzzy outputs in RAM. If the system has more than one system output, the WAV instruction is executed once for each system output.

### 9.3 Example Inference Kernel

**Figure 9-3** is a complete fuzzy inference kernel written in CPU12 assembly language. Numbers in square brackets are cycle counts for an HCS12 device. The kernel uses two system inputs with seven labels each and one system output with seven labels. The program assembles to 57 bytes. It executes in about 20  $\mu$ s at an 25-MHz bus rate. The basic structure can easily be extended to a general-purpose system with a larger number of inputs and outputs.

```

*
01 [2] FUZZIFY   LDX   #INPUT_MFS   ;Point at MF definitions
02 [2]          LDY   #FUZ_INS   ;Point at fuzzy input table
03 [3]          LDAA  CURRENT_INS ;Get first input value
04 [1]          LDAB  #7         ;7 labels per input
05 [5] GRAD_LOOP MEM          ;Evaluate one MF
06 [3]          DBNE  B,GRAD_LOOP ;For 7 labels of 1 input
07 [3]          LDAA  CURRENT_INS+1 ;Get second input value
08 [1]          LDAB  #7         ;7 labels per input
09 [5] GRAD_LOOP1 MEM         ;Evaluate one MF
10 [3]          DBNE  B,GRAD_LOOP1 ;For 7 labels of 1 input

11 [1]          LDAB  #7         ;Loop count

15 [2]          LDY   #FUZ_INS   ;Point at fuzzy ins and outs
16 [1]          LDAA  #$FFF      ;Init A (and clears V-bit)
17 [3n+4]      REV          ;Process rule list

18 [2] DEFUZ    LDY   #FUZ_OUT   ;Point at fuzzy outputs
19 [2]          LDX   #SGLTN_POS ;Point at singleton positions
20 [1]          LDAB  #7         ;7 fuzzy outs per COG output
21 [7b+4]      WAV          ;Calculate sums for wtd av
22 [11]        EDIV         ;Final divide for wtd av
23 [1]          TFR   Y,D        ;Move result to A:B
24 [3]          STAB  COG_OUT    ;Store system output
*
***** End

```

**Figure 9-3. Fuzzy Inference Engine**

Lines 1 to 3 set up pointers and load the system input value into the A accumulator.

Line 4 sets the loop count for the loop in lines 5 and 6.

Lines 5 and 6 make up the fuzzification loop for seven labels of one system input. The MEM instruction finds the y-value on a trapezoidal membership function for the current input value, for one label of the current input, and then stores the result to the corresponding fuzzy input. Pointers in X and Y are automatically updated by four and one so they point at the next membership function and fuzzy input respectively.

Line 7 loads the current value of the next system input. Pointers in X and Y already point to the right places as a result of the automatic update function of the MEM instruction in line 5.

Line 8 reloads a loop count.

Lines 9 and 10 form a loop to fuzzify the seven labels of the second system input. When the program drops to line 11, the Y index register is pointing at the next location after the last fuzzy input, which is the first fuzzy output in this system.

Line 11 sets the loop count to clear seven fuzzy outputs.

Lines 12 and 13 form a loop to clear all fuzzy outputs before rule evaluation starts.

Line 14 initializes the X index register to point at the first element in the rule list for the REV instruction.

Line 15 initializes the Y index register to point at the fuzzy inputs and outputs in the system. The rule list (for REV) consists of 8-bit offsets from this base address to particular fuzzy inputs or fuzzy outputs. The special value \$FE is interpreted by REV as a marker between rule antecedents and consequents.

Line 16 initializes the A accumulator to the highest 8-bit value in preparation for finding the smallest fuzzy input referenced by a rule antecedent. The LDAA #\$FF instruction also clears the V-bit in the CPU12's condition code register so the REV instruction knows it is processing antecedents. During rule list processing, the V bit is toggled each time an \$FE is detected in the list. The V bit indicates whether REV is processing antecedents or consequents.

Line 17 is the REV instruction, a self-contained loop to process successive elements in the rule list until an \$FF character is found. For a system of 17 rules with two antecedents and one consequent each, the REV instruction takes 259 cycles, but it is interruptible so it does not cause a long interrupt latency.

Lines 18 through 20 set up pointers and an iteration count for the WAV instruction.

Line 21 is the beginning of defuzzification. The WAV instruction calculates a sum-of-products and a sum-of-weights.

Line 22 completes defuzzification. The EDIV instruction performs a 32-bit by 16-bit divide on the intermediate results from WAV to get the weighted average.

Line 23 moves the EDIV result into the double accumulator.

Line 24 stores the low 8-bits of the defuzzification result.

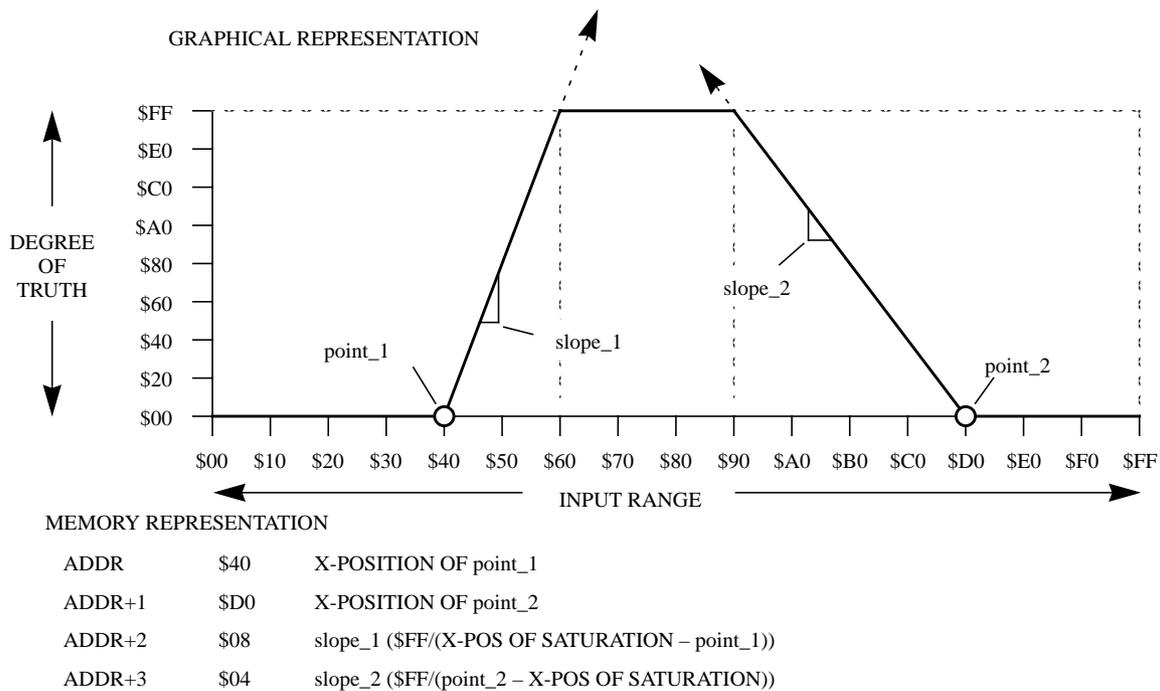

This example inference program shows how easy it is to incorporate fuzzy logic into general applications using the CPU12. Code space and execution time are no longer serious factors in the decision to use fuzzy logic. The next section begins a much more detailed look at the fuzzy logic instructions of the CPU12.

### 9.4 MEM Instruction Details

This section provides a more detailed explanation of the membership function evaluation instruction (MEM), including details about abnormal special cases for improperly defined membership functions.

#### 9.4.1 Membership Function Definitions

**Figure 9-4** shows how a normal membership function is specified in the CPU12. Typically, a software tool is used to input membership functions graphically, and the tool generates data structures for the target processor and software kernel. Alternatively, points and slopes for the membership functions can be determined and stored in memory with define-constant assembler directives.

**Figure 9-4. Defining a Normal Membership Function**

An internal CPU12 algorithm calculates the y-value where the current input intersects a membership function. This algorithm assumes the membership function obeys some common-sense rules. If the membership function definition is improper, the results may be unusual. See [9.4.2 Abnormal Membership Function Definitions](#) for a discussion of these cases.

These rules apply to normal membership functions.

- $\$00 \leq \text{point}_1 < \$FF$
- $\$00 < \text{point}_2 \leq \$FF$
- $\text{point}_1 < \text{point}_2$
- The sloping sides of the trapezoid meet at or above \$FF.

Each system input such as temperature has several labels such as cold, cool, normal, warm, and hot. Each label of each system input must have a membership function to describe its meaning in an unambiguous numerical way. Typically, there are three to seven labels per system input, but there is no practical restriction on this number as far as the fuzzification step is concerned.

## 9.4.2 Abnormal Membership Function Definitions

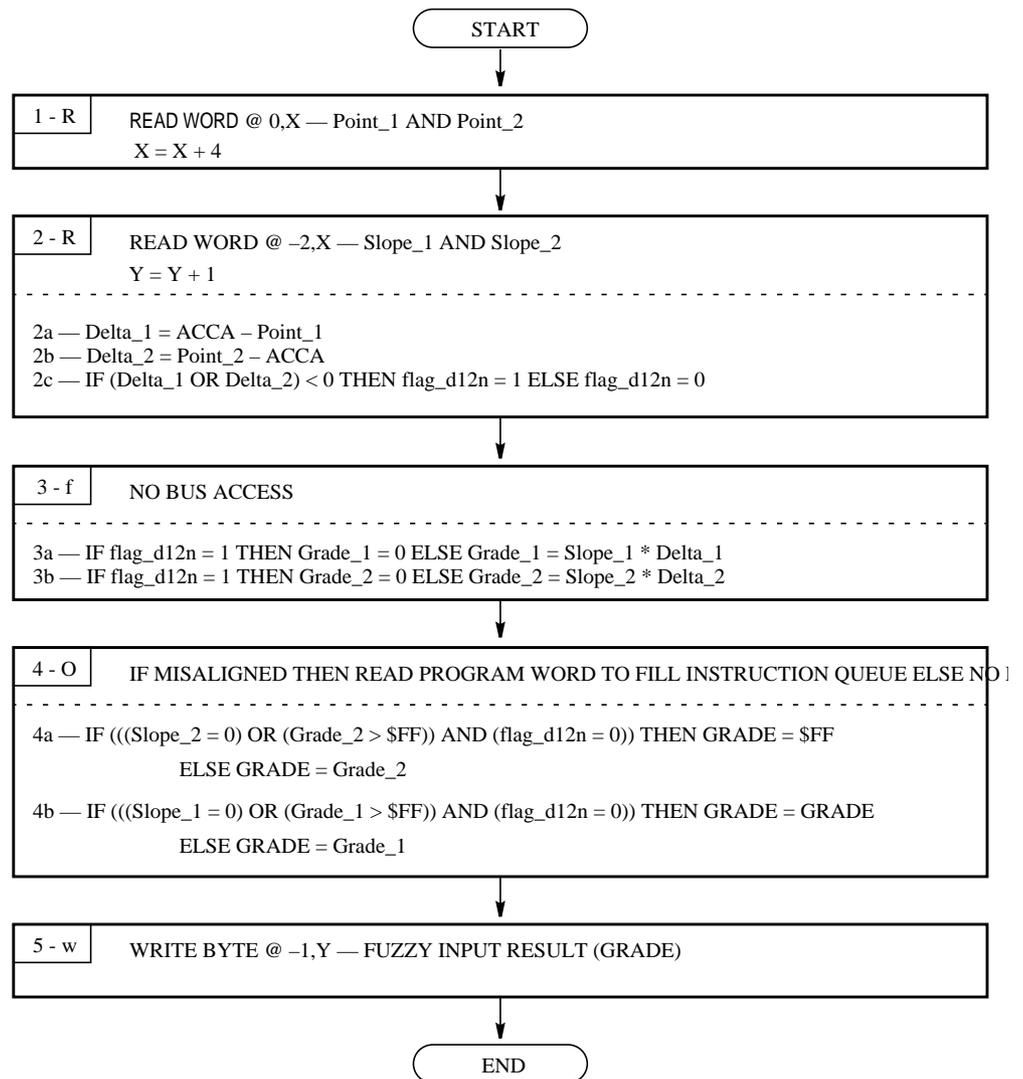

In the CPU12, it is possible (and proper) to define “crisp” membership functions. A crisp membership function has one or both sides vertical (infinite slope). Since the slope value \$00 is not used otherwise, it is assigned to mean infinite slope to the MEM instruction in the CPU12.

Although a good fuzzy development tool will not allow the user to specify an improper membership function, it is possible to have program errors or memory errors which result in erroneous abnormal membership functions. Although these abnormal shapes do not correspond to any working systems, understanding how the CPU12 treats these cases can be helpful for debugging.

A close examination of the MEM instruction algorithm will show how such membership functions are evaluated. [Figure 9-5](#) is a complete flow diagram for the execution of a MEM instruction. Each rectangular box represents one CPU12 bus cycle. The number in the upper left corner corresponds to the cycle number and the letter corresponds to the cycle type (refer to [Section 6. Instruction Glossary](#) for details). The upper portion of the box includes information about bus activity during this cycle (if any). The lower portion of the box, which is separated by a dashed line, includes information about internal CPU12 processes. It is common for several internal functions to take place during a single CPU12 cycle (for example, in cycle 2, two 8-bit subtractions take place and a flag is set based on the results).

Consider 4a:  $\text{If } (((\text{Slope\_2} = 0) \text{ or } (\text{Grade\_2} > \$\text{FF})) \text{ and } (\text{flag\_d12n} = 0)).$

The flag\_d12n is zero as long as the input value (in accumulator A) is within the trapezoid. Everywhere outside the trapezoid, one or the other delta term will be negative, and the flag will equal one. Slope\_2 equals zero indicates the right side of the trapezoid has infinite slope, so the resulting grade should be \$FF everywhere in the trapezoid, including at point\_2, as far as this side is concerned. The term grade\_2 greater than \$FF means the value is far enough into the trapezoid that the right sloping side of the trapezoid has crossed above the \$FF cutoff level and the resulting grade should be \$FF as far as the right sloping side is concerned. 4a decides if the value is left of the right sloping side (Grade = \$FF), or on the sloping portion of the right side of the trapezoid (Grade = Grade\_2). 4b could still override this tentative value in grade.

**Figure 9-5. MEM Instruction Flow Diagram**

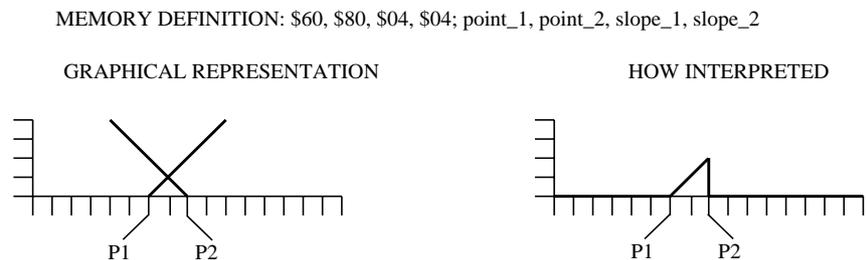

In 4b, slope\_1 is zero if the left side of the trapezoid has infinite slope (vertical). If so, the result (grade) should be \$FF at and to the right of point\_1 everywhere within the trapezoid as far as the left side is concerned. The grade\_1 greater than \$FF term corresponds to the input being to the right of where the left sloping side passes the \$FF cutoff level. If either of these conditions is true, the result (grade) is left at the value it got from 4a. The “else” condition in 4b corresponds to the input falling on the sloping portion of the left side of the trapezoid (or possibly outside the trapezoid), so the result is grade equal grade\_1. If the input was outside the trapezoid, flag\_d12n would be one and grade\_1 and

grade\_2 would have been forced to \$00 in cycle 3. The else condition of 4b would set the result to \$00.

The special cases shown here represent abnormal membership function definitions. The explanations describe how the specific algorithm in the CPU12 resolves these unusual cases. The results are not all intuitively obvious, but rather fall out from the specific algorithm. Remember, these cases should not occur in a normal system.

### 9.4.2.1 Abnormal Membership Function Case 1

This membership function is abnormal because the sloping sides cross below the \$FF cutoff level. The flag\_d12n signal forces the membership function to evaluate to \$00 everywhere except from point\_1 to point\_2. Within this interval, the tentative values for grade\_1 and grade\_2 calculated in cycle 3 fall on the crossed sloping sides. In step 4a, grade gets set to the grade\_2 value, but in 4b this is overridden by the grade\_1 value, which ends up as the result of the MEM instruction. One way to say this is that the result follows the left sloping side until the input passes point\_2, where the result goes to \$00.

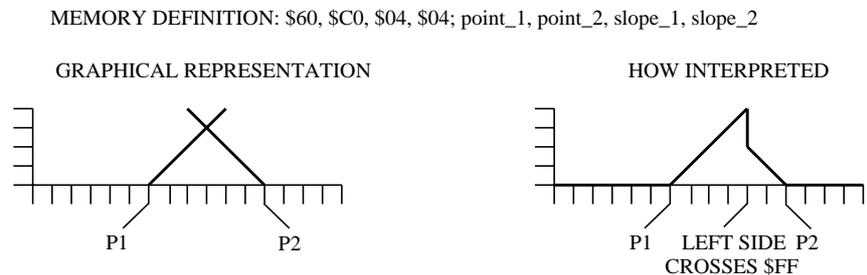

**Figure 9-6. Abnormal Membership Function Case 1**

If point\_1 was to the right of point\_2, flag\_d12n would force the result to be \$00 for all input values. In fact, flag\_d12n always limits the region of interest to the space greater than or equal to point\_1 and less than or equal to point\_2.

### 9.4.2.2 Abnormal Membership Function Case 2

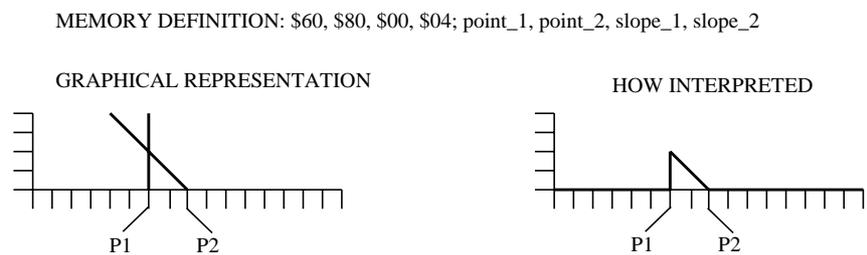

Like the previous example, the membership function in case 2 is abnormal because the sloping sides cross below the \$FF cutoff level, but the left sloping side reaches the \$FF cutoff level before the input gets to point\_2. In this case, the result follows the left sloping side until it reaches the \$FF cutoff level. At this point, the (grade\_1 > \$FF) term of 4b kicks in, making the expression true so grade equals grade (no overwrite). The result from here to point\_2 becomes controlled by the “else” part of 4a (grade = grade\_2), and the result follows the right sloping side.

**Figure 9-7. Abnormal Membership Function Case 2**

### 9.4.2.3 Abnormal Membership Function Case 3

The membership function in case 3 is abnormal because the sloping sides cross below the \$FF cutoff level, and the left sloping side has infinite slope. In this case, 4a is not true, so grade equals grade\_2. 4b is true because slope\_1 is zero, so 4b does not overwrite grade.

**Figure 9-8. Abnormal Membership Function Case 3**

## 9.5 REV and REVW Instruction Details

This section provides a more detailed explanation of the rule evaluation instructions (REV and REVW). The data structures used to specify rules are somewhat different for the weighted versus unweighted versions of the instruction. One uses 8-bit offsets in the encoded rules, while the other uses full 16-bit addresses. This affects the size of the rule data structure and execution time.

### 9.5.1 Unweighted Rule Evaluation (REV)

This instruction implements basic min-max rule evaluation. CPU12 registers are used for pointers and intermediate calculation results.

Since the REV instruction is essentially a list-processing instruction, execution time is dependent on the number of elements in the rule list. The REV instruction is interruptible (typically within three bus cycles), so it does not adversely affect worst case interrupt latency. Since all intermediate results and instruction status are held in stacked CPU12 registers, the interrupt service code can even include independent REV and REVW instructions.

#### 9.5.1.1 Set Up Prior to Executing REV

Some CPU12 registers and memory locations need to be set up prior to executing the REV instruction. X and Y index registers are used as index pointers to the rule list and the fuzzy inputs and outputs. The A accumulator is used for intermediate calculation results and needs to be set to \$FF initially. The V condition code bit is used as an instruction status indicator to show whether antecedents or consequents are being processed. Initially, the V bit is cleared to zero to indicate antecedents are being processed. The fuzzy outputs (working RAM locations) need to be cleared to \$00. If these values are not initialized before executing the REV instruction, results will be erroneous.

The X index register is set to the address of the first element in the rule list (in the knowledge base). The REV instruction automatically updates this pointer so that the instruction can resume correctly if it is interrupted. After the REV instruction finishes, X will point at the next address past the \$FF separator character that marks the end of the rule list.

The Y index register is set to the base address for the fuzzy inputs and outputs (in working RAM). Each rule antecedent is an unsigned 8-bit offset from this base address to the referenced fuzzy input. Each rule consequent is an unsigned 8-bit offset from this base address to the referenced fuzzy output. The Y index register remains constant throughout execution of the REV instruction.

The 8-bit A accumulator is used to hold intermediate calculation results during execution of the REV instruction. During antecedent processing, A starts out at \$FF and is replaced by any smaller fuzzy input that is referenced by a rule antecedent (MIN). During consequent processing, A holds the truth value for the rule. This truth value is stored to any fuzzy output that is referenced by a rule consequent, unless that fuzzy output is already larger (MAX).

Before starting to execute REV, A must be set to \$FF (the largest 8-bit value) because rule evaluation always starts with processing of the antecedents of the first rule. For subsequent rules in the list, A is automatically set to \$FF when the instruction detects the \$FE marker character between the last consequent of the previous rule and the first antecedent of a new rule.

The instruction LDAA #\$FF clears the V bit at the same time it initializes A to \$FF. This satisfies the REV setup requirement to clear the V bit as well as the requirement to initialize A to \$FF. Once the REV instruction starts, the value in the V bit is automatically maintained as \$FE separator characters are detected.

The final requirement to clear all fuzzy outputs to \$00 is part of the MAX algorithm. Each time a rule consequent references a fuzzy output, that fuzzy output is compared to the truth value for the current rule. If the current truth value is larger, it is written over the previous value in the fuzzy output. After all rules have been evaluated, the fuzzy output contains the truth value for the most-true rule that referenced that fuzzy output.

After REV finishes, A will hold the truth value for the last rule in the rule list. The V condition code bit should be one because the last element before the \$FF end marker should have been a rule consequent. If V is zero after executing REV, it indicates the rule list was structured incorrectly.

## 9.5.1.2 Interrupt Details

The REV instruction includes a 3-cycle processing loop for each byte in the rule list (including antecedents, consequents, and special separator characters). Within this loop, a check is performed to see if any qualified interrupt request is pending. If an interrupt is detected, the current CPU12 registers are stacked and the interrupt is honored. When the interrupt service routine finishes, an RTI instruction causes the CPU12 to recover its previous context from the stack, and the REV instruction is resumed as if it had not been interrupted.

The stacked value of the program counter (PC), in case of an interrupted REV instruction, points to the REV instruction rather than the instruction that follows. This causes the CPU12 to try to execute a new REV instruction upon return from the interrupt. Since the CPU12 registers (including the V bit in the condition codes register) indicate the current status of the interrupted REV instruction, this effectively causes the rule evaluation operation to resume from where it left off.

## 9.5.1.3 Cycle-by-Cycle Details for REV

The central element of the REV instruction is a 3-cycle loop that is executed once for each byte in the rule list. There is a small amount of housekeeping activity to get this loop started as REV begins and a small sequence to end the instruction. If an interrupt comes, there is a special small sequence to save CPU12 status on the stack before honoring the requested interrupt.

**Figure 9-9** is a REV instruction flow diagram. Each rectangular box represents one CPU12 clock cycle. Decision blocks and connecting arrows are considered to take no time at all. The letters in the small rectangles in the upper left corner of each bold box correspond to execution cycle codes (refer to **Section 6. Instruction Glossary** for details). Lower case letters indicate a cycle where 8-bit or no data is transferred. Upper case letters indicate cycles where 16-bit or no data is transferred.

When a value is read from memory, it cannot be used by the CPU12 until the second cycle after the read takes place. This is due to access and propagation delays.

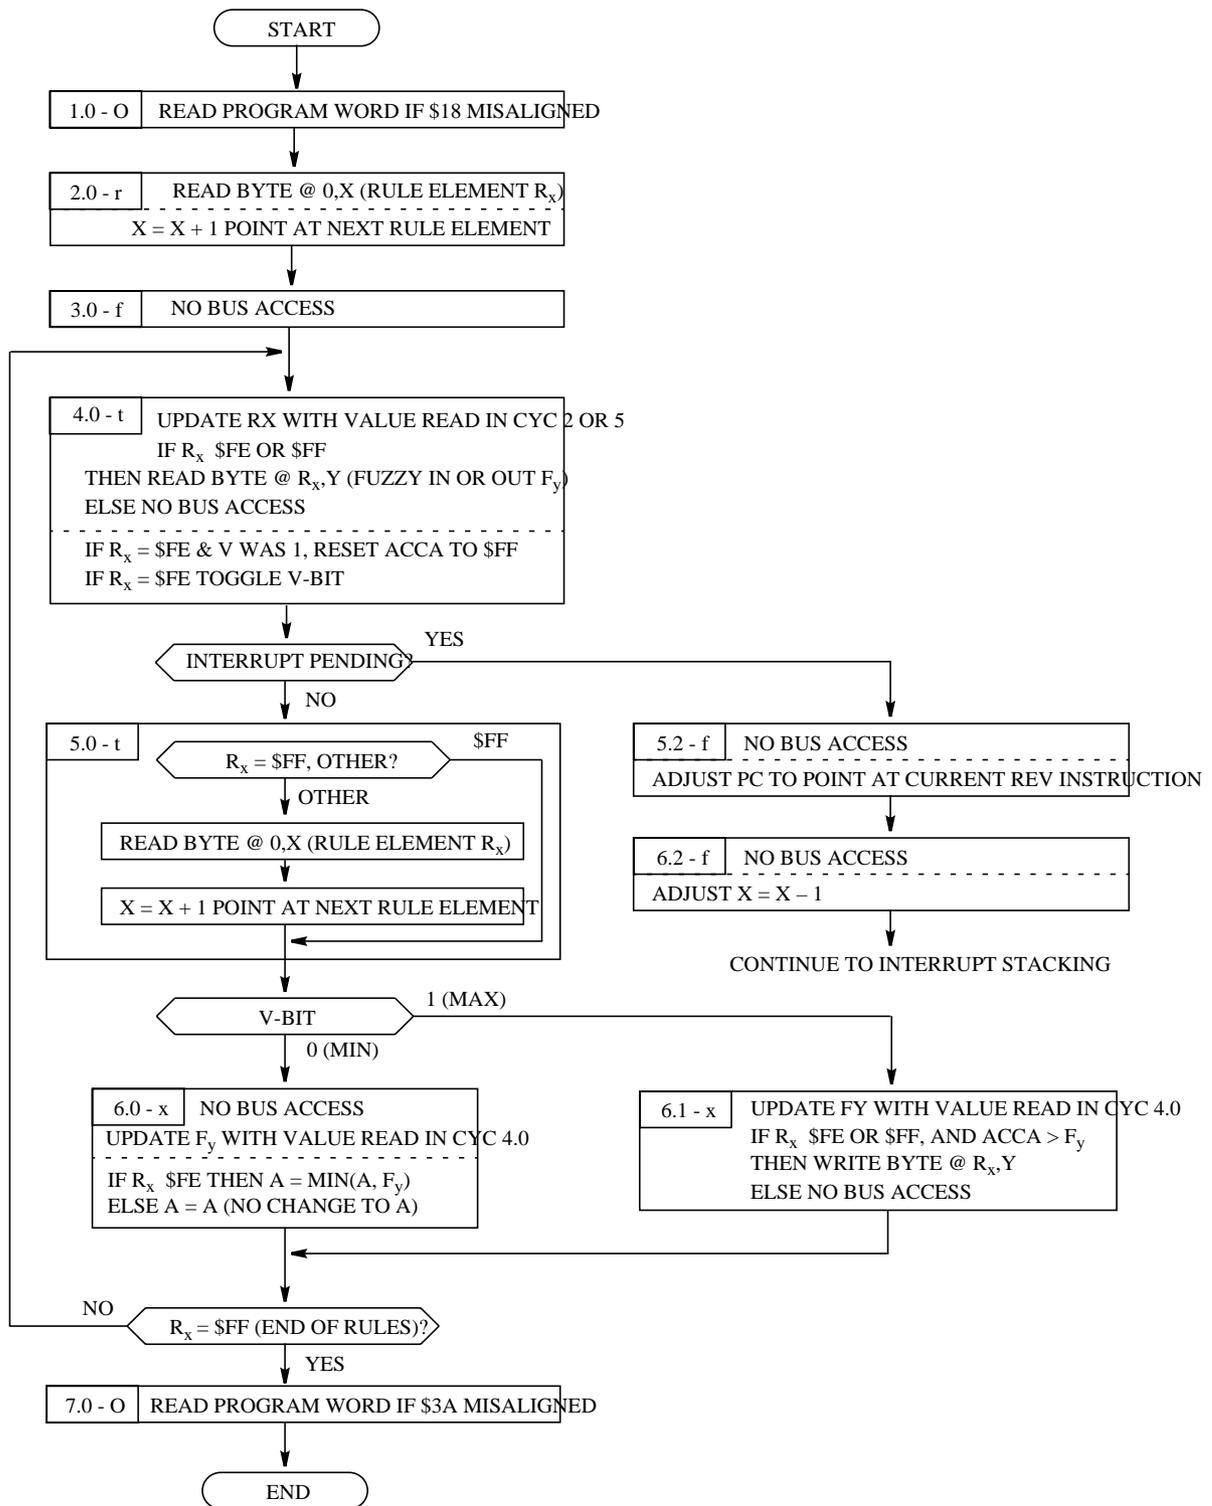

Figure 9-9. REV Instruction Flow Diagram

Since there is more than one flow path through the REV instruction, cycle numbers have a decimal place. This decimal place indicates which of several possible paths is being used. The CPU12 normally moves forward by one digit at a time within the same flow (flow number is indicated after the decimal point in the cycle number). There are two exceptions possible to this orderly sequence through an instruction. The first is a branch back to an earlier cycle number to form a loop as in 6.0 to 4.0. The second type of sequence change is from one flow to a parallel flow within the same instruction such as 4.0 to 5.2, which occurs if the REV instruction senses an interrupt. In this second type of sequence branch, the whole number advances by one and the flow number changes to a new value (the digit after the decimal point).

In cycle 1.0, the CPU12 does an optional program word access to replace the \$18 prebyte of the REV instruction. Notice that cycle 7.0 is also an O type cycle. One or the other of these will be a program word fetch, while the other will be a free cycle where the CPU12 does not access the bus. Although the \$18 page prebyte is a required part of the REV instruction, it is treated by the CPU12 as a somewhat separate single cycle instruction.

Rule evaluation begins at cycle 2.0 with a byte read of the first element in the rule list. Usually this would be the first antecedent of the first rule, but the REV instruction can be interrupted, so this could be a read of any byte in the rule list. The X index register is incremented so it points to the next element in the rule list. Cycle 3.0 is needed to satisfy the required delay between a read and when data is valid to the CPU12. Some internal CPU12 housekeeping activity takes place during this cycle, but there is no bus activity. By cycle 4.0, the rule element that was read in cycle 2.0 is available to the CPU12.

Cycle 4.0 is the first cycle of the main three cycle rule evaluation loop. Depending upon whether rule antecedents or consequents are being processed, the loop will consist of cycles 4.0, 5.0, 6.0, or the sequence 4.0, 5.0, 6.1. This loop is executed once for every byte in the rule list, including the \$FE separators and the \$FF end-of-rules marker.

At each cycle 4.0, a fuzzy input or fuzzy output is read, except during the loop passes associated with the \$FE and \$FF marker bytes, where no bus access takes place during cycle 4.0. The read access uses the Y index register as the base address and the previously read rule byte ( $R_x$ ) as an unsigned offset from Y. The fuzzy input or output value read here

will be used during the next cycle 6.0 or 6.1. Besides being used as the offset from Y for this read, the previously read  $R_x$  is checked to see if it is a separator character (\$FE). If  $R_x$  was \$FE and the V bit was one, this indicates a switch from processing consequents of one rule to starting to process antecedents of the next rule. At this transition, the A accumulator is initialized to \$FF to prepare for the min operation to find the smallest fuzzy input. Also, if  $R_x$  is \$FE, the V bit is toggled to indicate the change from antecedents to consequents, or consequents to antecedents.

During cycle 5.0, a new rule byte is read unless this is the last loop pass, and  $R_x$  is \$FF (marking the end of the rule list). This new rule byte will not be used until cycle 4.0 of the next pass through the loop.

Between cycle 5.0 and 6.x, the V-bit is used to decide which of two paths to take. If V is zero, antecedents are being processed and the CPU12 progresses to cycle 6.0. If V is one, consequents are being processed and the CPU12 goes to cycle 6.1.

During cycle 6.0, the current value in the A accumulator is compared to the fuzzy input that was read in the previous cycle 4.0, and the lower value is placed in the A accumulator (min operation). If  $R_x$  is \$FE, this is the transition between rule antecedents and rule consequents, and this min operation is skipped (although the cycle is still used). No bus access takes place during cycle 6.0 but cycle 6.x is considered an x type cycle because it could be a byte write (cycle 6.1) or a free cycle (cycle 6.0 or 6.1 with  $R_x = \$FE$  or \$FF).

If an interrupt arrives while the REV instruction is executing, REV can break between cycles 4.0 and 5.0 in an orderly fashion so that the rule evaluation operation can resume after the interrupt has been serviced. Cycles 5.2 and 6.2 are needed to adjust the PC and X index register so the REV operation can recover after the interrupt. PC is adjusted backward in cycle 5.2 so it points to the currently running REV instruction. After the interrupt, rule evaluation will resume, but the values that were stored on the stack for index registers, accumulator A, and CCR will cause the operation to pick up where it left off. In cycle 6.2, the X index register is adjusted backward by one because the last rule byte needs to be re-fetched when the REV instruction resumes.

After cycle 6.2, the REV instruction is finished, and execution would continue to the normal interrupt processing flow.

## 9.5.2 Weighted Rule Evaluation (RE VW)

This instruction implements a weighted variation of min-max rule evaluation. The weighting factors are stored in a table with one 8-bit entry per rule. The weight is used to multiply the truth value of the rule (minimum of all antecedents) by a value from zero to one to get the weighted result. This weighted result is then applied to the consequents, just as it would be for unweighted rule evaluation.

Since the RE VW instruction is essentially a list-processing instruction, execution time is dependent on the number of rules and the number of elements in the rule list. The RE VW instruction is interruptible (typically within three to five bus cycles), so it does not adversely affect worst case interrupt latency. Since all intermediate results and instruction status are held in stacked CPU12 registers, the interrupt service code can even include independent RE V and RE VW instructions.

The rule structure is different for RE VW than for RE V. For RE VW, the rule list is made up of 16-bit elements rather than 8-bit elements. Each antecedent is represented by the full 16-bit address of the corresponding fuzzy input. Each rule consequent is represented by the full address of the corresponding fuzzy output.

The markers separating antecedents from consequents are the reserved 16-bit value \$FFFE, and the end of the last rule is marked by the reserved 16-bit value \$FFFF. Since \$FFFE and \$FFFF correspond to the addresses of the reset vector, there would never be a fuzzy input or output at either of these locations.

### 9.5.2.1 Set Up Prior to Executing RE VW

Some CPU12 registers and memory locations need to be set up prior to executing the RE VW instruction. X and Y index registers are used as index pointers to the rule list and the list of rule weights. The A accumulator is used for intermediate calculation results and needs to be set to \$FF initially. The V condition code bit is used as an instruction status indicator that shows whether antecedents or consequents are being processed. Initially the V bit is cleared to zero to indicate antecedents are being processed. The C condition code bit is used to indicate whether rule weights are to be used (1) or not (0). The fuzzy outputs (working RAM locations) need to be cleared to \$00. If these values are not initialized before executing the RE VW instruction, results will be erroneous.

The X index register is set to the address of the first element in the rule list (in the knowledge base). The REVW instruction automatically updates this pointer so that the instruction can resume correctly if it is interrupted. After the REVW instruction finishes, X will point at the next address past the \$FFFF separator word that marks the end of the rule list.

The Y index register is set to the starting address of the list of rule weights. Each rule weight is an 8-bit value. The weighted result is the truncated upper eight bits of the 16-bit result, which is derived by multiplying the minimum rule antecedent value (\$00–\$FF) by the weight plus one (\$001–\$100). This method of weighting rules allows an 8-bit weighting factor to represent a value between zero and one inclusive.

The 8-bit A accumulator is used to hold intermediate calculation results during execution of the REVW instruction. During antecedent processing, A starts out at \$FF and is replaced by any smaller fuzzy input that is referenced by a rule antecedent. If rule weights are enabled by the C condition code bit equal one, the rule truth value is multiplied by the rule weight just before consequent processing starts. During consequent processing, A holds the truth value (possibly weighted) for the rule. This truth value is stored to any fuzzy output that is referenced by a rule consequent, unless that fuzzy output is already larger (MAX).

Before starting to execute REVW, A must be set to \$FF (the largest 8-bit value) because rule evaluation always starts with processing of the antecedents of the first rule. For subsequent rules in the list, A is automatically set to \$FF when the instruction detects the \$FFFE marker word between the last consequent of the previous rule, and the first antecedent of a new rule.

Both the C and V condition code bits must be set up prior to starting a REVW instruction. Once the REVW instruction starts, the C bit remains constant and the value in the V bit is automatically maintained as \$FFFE separator words are detected.

The final requirement to clear all fuzzy outputs to \$00 is part of the MAX algorithm. Each time a rule consequent references a fuzzy output, that fuzzy output is compared to the truth value (weighted) for the current rule. If the current truth value is larger, it is written over the previous value in the fuzzy output. After all rules have been evaluated, the fuzzy output contains the truth value for the most-true rule that referenced that fuzzy output.

After REVW finishes, A will hold the truth value (weighted) for the last rule in the rule list. The V condition code bit should be one because the last element before the \$FFFF end marker should have been a rule consequent. If V is zero after executing REVW, it indicates the rule list was structured incorrectly.

### 9.5.2.2 Interrupt Details

The REVW instruction includes a 3-cycle processing loop for each word in the rule list (this loop expands to five cycles between antecedents and consequents to allow time for the multiplication with the rule weight). Within this loop, a check is performed to see if any qualified interrupt request is pending. If an interrupt is detected, the current CPU12 registers are stacked and the interrupt is honored. When the interrupt service routine finishes, an RTI instruction causes the CPU12 to recover its previous context from the stack, and the REVW instruction is resumed as if it had not been interrupted.

The stacked value of the program counter (PC), in case of an interrupted REVW instruction, points to the REVW instruction rather than the instruction that follows. This causes the CPU12 to try to execute a new REVW instruction upon return from the interrupt. Since the CPU12 registers (including the C bit and V bit in the condition codes register) indicate the current status of the interrupted REVW instruction, this effectively causes the rule evaluation operation to resume from where it left off.

### 9.5.2.3 Cycle-by-Cycle Details for REVW

The central element of the REVW instruction is a 3-cycle loop that is executed once for each word in the rule list. For the special case pass (where the \$FFFE separator word is read between the rule antecedents and the rule consequents, and weights are enabled by the C bit equal one), this loop takes five cycles. There is a small amount of housekeeping activity to get this loop started as REVW begins and a small sequence to end the instruction. If an interrupt comes, there is a special small sequence to save CPU12 status on the stack before the interrupt is serviced.

**Figure 9-10** is a detailed flow diagram for the REVW instruction. Each rectangular box represents one CPU12 clock cycle. Decision blocks and connecting arrows are considered to take no time at all. The letters in the small rectangles in the upper left corner of each bold box correspond to the execution cycle codes (refer to **Section 6. Instruction Glossary** for details). Lower case letters indicate a cycle where 8-bit or no data is transferred. Upper case letters indicate cycles where 16-bit data could be transferred.

In cycle 2.0, the first element of the rule list (a 16-bit address) is read from memory. Due to propagation delays, this value cannot be used for calculations until two cycles later (cycle 4.0). The X index register, which is used to access information from the rule list, is incremented by two to point at the next element of the rule list.

The operations performed in cycle 4.0 depend on the value of the word read from the rule list. \$FFFE is a special token that indicates a transition from antecedents to consequents or from consequents to antecedents of a new rule. The V bit can be used to decide which transition is taking place, and V is toggled each time the \$FFFE token is detected. If V was zero, a change from antecedents to consequents is taking place, and it is time to apply weighting (provided it is enabled by the C bit equal one). The address in TMP2 (derived from Y) is used to read the weight byte from memory. In this case, there is no bus access in cycle 5.0, but the index into the rule list is updated to point to the next rule element.

The old value of X ( $X_0$ ) is temporarily held on internal nodes, so it can be used to access a rule word in cycle 7.2. The read of the rule word is timed to start two cycles before it will be used in cycle 4.0 of the next loop pass. The actual multiply takes place in cycles 6.2 through 8.2. The 8-bit weight from memory is incremented (possibly overflowing to \$100) before the multiply, and the upper eight bits of the 16-bit internal result is used as the weighted result. By using weight+1, the result can range from 0.0 times A to 1.0 times A. After 8.2, flow continues to the next loop pass at cycle 4.0.

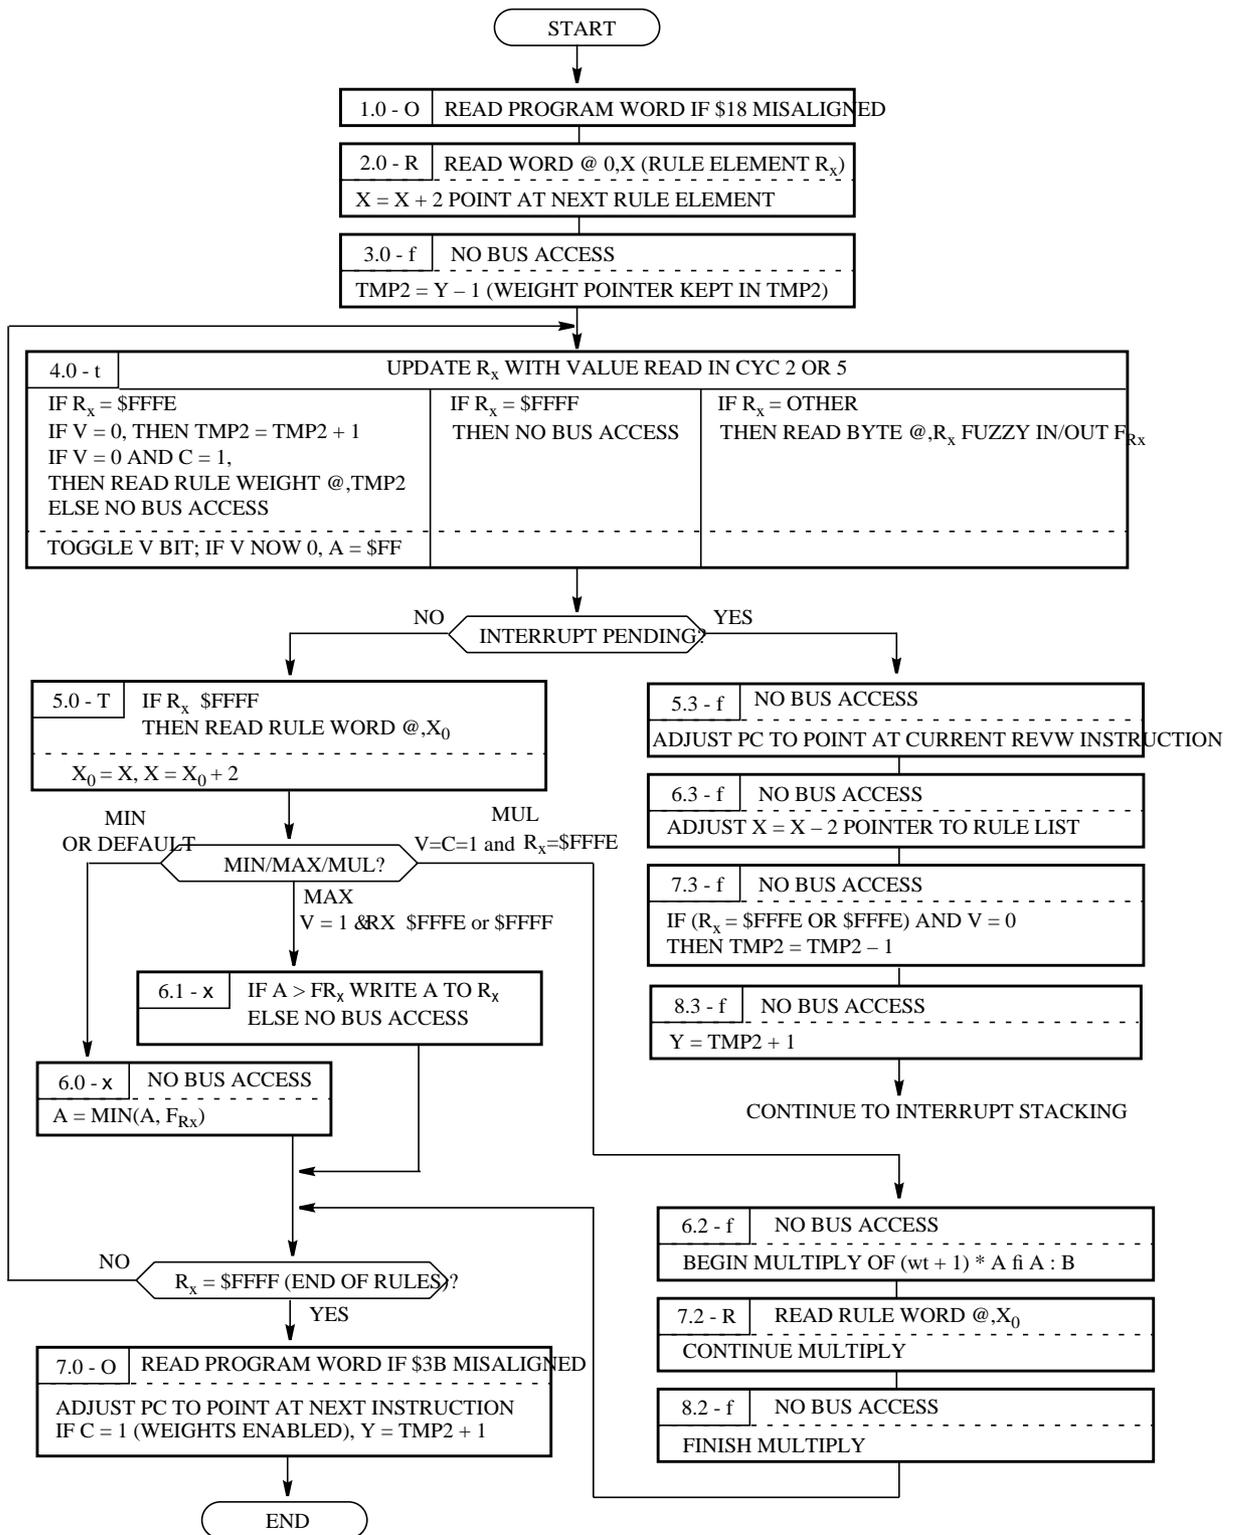

Figure 9-10. REVW Instruction Flow Diagram

At cycle 4.0, if  $R_x$  is \$FFFE and V was one, a change from consequents to antecedents of a new rule is taking place, so accumulator A must be reinitialized to \$FF. During processing of rule antecedents, A is updated with the smaller of A, or the current fuzzy input (cycle 6.0). Cycle 5.0 is usually used to read the next rule word and update the pointer in X. This read is skipped if the current  $R_x$  is \$FFFF (end of rules mark). If this is a weight multiply pass, the read is delayed until cycle 7.2. During processing of consequents, cycle 6.1 is used to optionally update a fuzzy output if the value in accumulator A is larger.

After all rules have been processed, cycle 7.0 is used to update the PC to point at the next instruction. If weights were enabled, Y is updated to point at the location that immediately follows the last rule weight.

## 9.6 WAV Instruction Details

The WAV instruction performs weighted average calculations used in defuzzification. The pseudo-instruction wavr is used to resume an interrupted weighted average operation. WAV calculates the numerator and denominator sums using:

$$\text{System Output} = \frac{\sum_{i=1}^n S_i F_i}{\sum_{i=1}^n F_i}$$

Where n is the number of labels of a system output,  $S_i$  are the singleton positions from the knowledge base, and  $F_i$  are fuzzy outputs from RAM.  $S_i$  and  $F_i$  are 8-bit values. The 8-bit B accumulator holds the iteration count n. Internal temporary registers hold intermediate sums, 24 bits for the numerator and 16 bits for the denominator. This makes this instruction suitable for n values up to 255 although eight is a more typical value. The final long division is performed with a separate EDIV instruction immediately after the WAV instruction. The WAV instruction returns the numerator and denominator sums in the correct registers for the EDIV. (EDIV performs the unsigned division  $Y = Y : D / X$ ; remainder in D.)

Execution time for this instruction depends on the number of iterations (labels for the system output). WAV is interruptible so that worst case interrupt latency is not affected by the execution time for the complete weighted average operation. WAV includes initialization for the 24-bit and 16-bit partial sums so the first entry into WAV looks different than a resume from interrupt operation. The CPU12 handles this difficulty with a pseudo-instruction (*wavr*), which is specifically intended to resume an interrupted weighted average calculation. Refer to [9.6.3 Cycle-by-Cycle Details for WAV and \*wavr\*](#) for more detail.

### 9.6.1 Set Up Prior to Executing WAV

Before executing the WAV instruction, index registers X and Y and accumulator B must be set up. Index register X is a pointer to the  $S_i$  singleton list. X must have the address of the first singleton value in the knowledge base. Index register Y is a pointer to the fuzzy outputs  $F_i$ . Y must have the address of the first fuzzy output for this system output. B is the iteration count n. The B accumulator must be set to the number of labels for this system output.

### 9.6.2 WAV Interrupt Details

The WAV instruction includes a 7-cycle processing loop for each label of the system output (8 cycles in M68HC12). Within this loop, the CPU12 checks whether a qualified interrupt request is pending. If an interrupt is detected, the current values of the internal temporary registers for the 24-bit and 16-bit sums are stacked, the CPU12 registers are stacked, and the interrupt is serviced.

A special processing sequence is executed when an interrupt is detected during a weighted average calculation. This exit sequence adjusts the PC so that it points to the second byte of the WAV object code ( $\$3C$ ), before the PC is stacked. Upon return from the interrupt, the  $\$3C$  value is interpreted as a *wavr* pseudo-instruction. The *wavr* pseudo-instruction causes the CPU12 to execute a special WAV resumption sequence. The *wavr* recovery sequence adjusts the PC so that it looks like it did during execution of the original WAV instruction, then jumps back into the WAV processing loop. If another interrupt occurs before the weighted average calculation finishes, the PC is adjusted again as it was for the first interrupt. WAV can be interrupted any number of times, and additional WAV instructions can be executed while a WAV instruction is interrupted.

### 9.6.3 Cycle-by-Cycle Details for WAV and wavr

The WAV instruction is unusual in that the logic flow has two separate entry points. The first entry point is the normal start of a WAV instruction. The second entry point is used to resume the weighted average operation after a WAV instruction has been interrupted. This recovery operation is called the wavr pseudo-instruction.

**Figure 9-12** is a flow diagram of the WAV instruction in the HCS12, including the wavr pseudo-instruction. **Figure 9-12** is a flow diagram of the WAV instruction in the M68HC12, including the wavr pseudo-instruction. Each rectangular box in these figures represents one CPU12 clock cycle. Decision blocks and connecting arrows are considered to take no time at all. The letters in the small rectangles in the upper left corner of the boxes correspond to execution cycle codes (refer to **Section 6. Instruction Glossary** for details). Lower case letters indicate a cycle where 8-bit or no data is transferred. Upper case letters indicate cycles where 16-bit data could be transferred.

The cycle-by-cycle description provided here refers to the HCS12 flow in **Figure 9-11**. In terms of cycle-by-cycle bus activity, the \$18 page select prebyte is treated as a special 1-byte instruction. In cycle 1.0 of the WAV instruction, one word of program information will be fetched into the instruction queue if the \$18 is located at an odd address. If the \$18 is at an even address, the instruction queue cannot advance so there is no bus access in this cycle.

In cycle 2.0, three internal 16-bit temporary registers are cleared in preparation for summation operations, but there is no bus access. The WAV instruction maintains a 32-bit sum-of-products in TMP1 : TMP2 and a 16-bit sum-of-weights in TMP3. By keeping these sums inside the CPU12, bus accesses are reduced and the WAV operation is optimized for high speed.

Cycles 3.0 through 9.0 form the 7-cycle main loop for WAV. The value in the 8-bit B accumulator is used to count the number of loop iterations. B is decremented at the top of the loop in cycle 3.0, and the test for zero is located at the bottom of the loop after cycle 9.0. Cycle 4.0 and 5.0 are used to fetch the 8-bit operands for one iteration of the loop. X and Y index registers are used to access these operands. The index registers are incremented as the operands are fetched. Cycle 6.0 is used to accumulate the current fuzzy output into TMP3. Cycles 7.0 through 9.0 are used to perform the eight by eight multiply of  $F_i$  times  $S_i$ , and

accumulate this result into  $TMP1 : TMP2$ . Even though the sum-of-products will not exceed 24 bits, the sum is maintained in the 32-bit combined  $TMP1 : TMP2$  register because it is easier to use existing 16-bit operations than it would be to create a new smaller operation to handle the high order bits of this sum.

Since the weighted average operation could be quite long, it is made to be interruptible. The usual longest latency path is from very early in cycle 6.0, through cycle 9.0, to the top of the loop to cycle 3.0, through cycle 5.0 to the interrupt check.

If the WAV instruction is interrupted, the internal temporary registers  $TMP3$ ,  $TMP2$ , and  $TMP1$  need to be stored on the stack so the operation can be resumed. Since the WAV instruction included initialization in cycle 2.0, the recovery path after an interrupt needs to be different. The `wavr` pseudo-instruction has the same opcode as WAV, but it is on the first page of the opcode map so there is no page prebyte (\$18) like there is for WAV. When WAV is interrupted, the PC is adjusted to point at the second byte of the WAV object code, so that it will be interpreted as the `wavr` pseudo-instruction on return from the interrupt, rather than the WAV instruction. During the recovery sequence, the PC is readjusted in case another interrupt comes before the weighted average operation finishes.

The resume sequence includes recovery of the temporary registers from the stack (1.1 through 3.1), and reads to get the operands for the current iteration. The normal WAV flow is then rejoined at cycle 6.0.

Upon normal completion of the instruction (cycle 10.0), the PC is adjusted so it points to the next instruction. The results are transferred from the  $TMP$  registers into CPU12 registers in such a way that the EDIV instruction can be used to divide the sum-of-products by the sum-of-weights.  $TMP1 : TMP2$  is transferred into  $Y : D$  and  $TMP3$  is transferred into  $X$ .

**Figure 9-12. WAV and wavr Instruction Flow Diagram (for M68HC12)**

## 9.7 Custom Fuzzy Logic Programming

The basic fuzzy logic inference techniques described earlier are suitable for a broad range of applications, but some systems may require customization. The built-in fuzzy instructions use 8-bit resolution and some systems may require finer resolution. The rule evaluation instructions only support variations of MIN-MAX rule evaluation and other methods have been discussed in fuzzy logic literature. The weighted average of singletons is not the only defuzzification technique. The CPU12 has several instructions and addressing modes that can be helpful when developing custom fuzzy logic systems.

### 9.7.1 Fuzzification Variations

The MEM instruction supports trapezoidal membership functions and several other varieties, including membership functions with vertical sides (infinite slope sides). Triangular membership functions are a subset of trapezoidal functions. Some practitioners refer to s-, z-, and  $\pi$ -shaped membership functions. These refer to a trapezoid butted against the right end of the x-axis, a trapezoid butted against the left end of the x-axis, and a trapezoidal membership function that isn't butted against either end of the x-axis, respectively. Many other membership function shapes are possible, if memory space and processing bandwidth are sufficient.

Tabular membership functions offer complete flexibility in shape and very fast evaluation time. However, tables take a very large amount of memory space (as many as 256 bytes per label of one system input). The excessive size to specify tabular membership functions makes them impractical for most microcontroller-based fuzzy systems. The CPU12 instruction set includes two instructions (TBL and ETBL) for lookup and interpolation of compressed tables.

The TBL instruction uses 8-bit table entries (y-values) and returns an 8-bit result. The ETBL instruction uses 16-bit table entries (y-values) and returns a 16-bit result. A flexible indexed addressing mode is used to identify the effective address of the data point at the beginning of the line segment, and the data value for the end point of the line segment is the next consecutive memory location (byte for TBL and word for ETBL). In both cases, the B accumulator represents the ratio of (the x-distance from the beginning of the line segment to the lookup point) to (the

x-distance from the beginning of the line segment to the end of the line segment). B is treated as an 8-bit binary fraction with radix point left of the MSB, so each line segment can effectively be divided into 256 pieces. During execution of the TBL or ETBL instruction, the difference between the end point y-value and the beginning point y-value (a signed byte-TBL or word-ETBL) is multiplied by the B accumulator to get an intermediate delta-y term. The result is the y-value of the beginning point, plus this signed intermediate delta-y value.

Because indexed addressing mode is used to identify the starting point of the line segment of interest, there is a great deal of flexibility in constructing tables. A common method is to break the x-axis range into 256 equal width segments and store the y value for each of the resulting 257 endpoints. The 16-bit D accumulator is then used as the x input to the table. The upper eight bits (A) is used as a coarse lookup to find the line segment of interest, and the lower eight bits (B) is used to interpolate within this line segment.

In the program sequence

```
LDX      #TBL_START
LDD      DATA_IN
TBL      A, X
```

The notation A,X causes the TBL instruction to use the A<sup>th</sup> line segment in the table. The low-order half of D (B) is used by TBL to calculate the exact data value from this line segment. This type of table uses only 257 entries to approximate a table with 16 bits of resolution. This type of table has the disadvantage of equal width line segments, which means just as many points are needed to describe a flat portion of the desired function as are needed for the most active portions.

Another type of table stores x:y coordinate pairs for the endpoints of each linear segment. This type of table may reduce the table storage space compared to the previous fixed-width segments because flat areas of the functions can be specified with a single pair of endpoints. This type of table is a little harder to use with the CPU12 TBL and ETBL instructions because the table instructions expect y-values for segment endpoints to be in consecutive memory locations.

Consider a table made up of an arbitrary number of x:y coordinate pairs, where all values are eight bits. The table is entered with the x-coordinate of the desired point to lookup in the A accumulator. When the table is exited, the corresponding y-value is in the A accumulator. **Figure 9-13** shows one way to work with this type of table.

```

BEGIN      LDY      #TABLE_START-2      ;setup initial table pointer
FIND_LOOP  CMPA     2,+Y                  ;find first Xn > XL

           PSHA                    ;now YB@0,SP and YE@1,SP
           TBL     2,SP+                ;interpolate and deallocate
                                           ;stack temps
  
```

**Figure 9-13. Endpoint Table Handling**

The basic idea is to find the segment of interest, temporarily build a 1-segment table of the correct format on the stack, then use TBL with stack relative indexed addressing to interpolate. The most difficult part of the routine is calculating the proportional distance from the beginning of the segment to the lookup point versus the width of the segment  $((XL-XB)/(XE-XB))$ . With this type of table, this calculation must be done at run time. In the previous type of table, this proportional term is an inherent part (the lowest order bits) of the data input to the table.

Some fuzzy theorists have suggested membership functions should be shaped like normal distribution curves or other mathematical functions. This may be correct, but the processing requirements to solve for an intercept on such a function would be unacceptable for most microcontroller-based fuzzy systems. Such a function could be encoded into a table of one of the previously described types.

For many common systems, the thing that is most important about membership function shape is that there is a gradual transition from non-membership to membership as the system input value approaches the central range of the membership function.

Examine the human problem of stopping a car at an intersection. Rules such as “If intersection is close and speed is fast, apply brakes” might be used. The meaning (reflected in membership function shape and position) of the labels “close” and “fast” will be different for a teenager than they are for a grandmother, but both can accomplish the goal of stopping. It makes intuitive sense that the exact shape of a membership function is much less important than the fact that it has gradual boundaries.

### 9.7.2 Rule Evaluation Variations

The REV and REVW instructions expect fuzzy input and fuzzy output values to be 8-bit values. In a custom fuzzy inference program, higher resolution may be desirable (although this is not a common requirement). The CPU12 includes variations of minimum and maximum operations that work with the fuzzy MIN-MAX inference algorithm. The problem with the fuzzy inference algorithm is that the min and max operations need to store their results differently, so the min and max instructions must work differently or more than one variation of these instructions is needed.

The CPU12 has MIN and MAX instructions for 8- or 16-bit operands, where one operand is in an accumulator and the other is a referenced memory location. There are separate variations that replace the accumulator or the memory location with the result. While processing rule antecedents in a fuzzy inference program, a reference value must be compared to each of the referenced fuzzy inputs, and the smallest input must end up in an accumulator. The instruction

```
EMIND    2,X+    ;process one rule antecedent
```

automates the central operations needed to process rule antecedents. The E stands for extended, so this instruction compares 16-bit operands. The D at the end of the mnemonic stands for the D accumulator, which is both the first operand for the comparison and the destination of the result. The 2,X+ is an indexed addressing specification that says X points to the second operand for the comparison and it will be post-incremented by 2 to point at the next rule antecedent.

When processing rule consequents, the operand in the accumulator must remain constant (in case there is more than one consequent in the rule), and the result of the comparison must replace the referenced fuzzy output in RAM. To do this, use the instruction

```
EMAXM      2,X+      ;process one rule consequent
```

The M at the end of the mnemonic indicates that the result will replace the referenced memory operand. Again, indexed addressing is used. These two instructions would form the working part of a 16-bit resolution fuzzy inference routine.

There are many other methods of performing inference, but none of these are as widely used as the min-max method. Since the CPU12 is a general-purpose microcontroller, the programmer has complete freedom to program any algorithm desired. A custom programmed algorithm would typically take more code space and execution time than a routine that used the built-in REV or REVW instructions.

### 9.7.3 Defuzzification Variations

Other CPU12 instructions can help with custom defuzzification routines in two main areas:

- The first case is working with operands that are more than eight bits.
- The second case involves using an entirely different approach than weighted average of singletons.

The primary part of the WAV instruction is a multiply and accumulate operation to get the numerator for the weighted average calculation. When working with operands as large as 16 bits, the EMACS instruction could at least be used to automate the multiply and accumulate function. The CPU12 has extended math capabilities, including the EMACS instruction which uses 16-bit input operands and accumulates the sum to a 32-bit memory location and 32-bit by 16-bit divide instructions.

One benefit of the WAV instruction is that both a sum of products and a sum of weights are maintained, while the fuzzy output operand is only accessed from memory once. Since memory access time is such a significant part of execution time, this provides a speed advantage compared to conventional instructions.

The weighted average of singletons is the most commonly used technique in microcontrollers because it is computationally less difficult than most other methods. The simplest method is called max defuzzification, which simply uses the largest fuzzy output as the system result. However, this approach does not take into account any other fuzzy outputs, even when they are almost as true as the chosen max output. Max defuzzification is not a good general choice because it only works for a subset of fuzzy logic applications.

The CPU12 is well suited for more computationally challenging algorithms than weighted average. A 32-bit by 16-bit divide instruction takes 11 or 12 25-MHz cycles for unsigned or signed variations. A 16-bit by 16-bit multiply with a 32-bit result takes only three 25-MHz cycles. The EMACS instruction uses 16-bit operands and accumulates the result in a 32-bit memory location, taking only 12 25-MHz cycles per iteration, including accessing all operands from memory and storing the result to memory.

## Appendix A. Instruction Reference

### A.1 Introduction

This appendix provides quick references for the instruction set, opcode map, and encoding.

### A.3 Interrupt Vector Locations

\$FFFE, \$FFFF	Power-On (POR) or External Reset
\$FFFC, \$FFFD	Clock Monitor Reset
\$FFFA, \$FFFB	Computer Operating Properly (COP Watchdog Reset)
\$FFF8, \$FFF9	Unimplemented Opcode Trap
\$FFF6, \$FFF7	Software Interrupt Instruction (SWI)
\$FFF4, \$FFF5	XIRQ
\$FFF2, \$FFF3	IRQ
\$FF00–\$FFF1	Device-Specific Interrupt Sources

### A.4 Notation Used in Instruction Set Summary

#### CPU12 Register Notation

Accumulator A — A or a	Index Register Y — Y or y
Accumulator B — B or b	Stack Pointer — SP, sp, or s
Accumulator D — D or d	Program Counter — PC, pc, or p
Index Register X — X or x	Condition Code Register — CCR or c

#### Explanation of Italic Expressions in Source Form Column

<i>abc</i>	— A or B or CCR
<i>abcdxys</i>	— A or B or CCR or D or X or Y or SP. Some assemblers also allow T2 or T3.
<i>abd</i>	— A or B or D
<i>abdxys</i>	— A or B or D or X or Y or SP
<i>dxys</i>	— D or X or Y or SP
<i>msk8</i>	— 8-bit mask, some assemblers require # symbol before value
<i>opr8i</i>	— 8-bit immediate value
<i>opr16i</i>	— 16-bit immediate value
<i>opr8a</i>	— 8-bit address used with direct address mode
<i>opr16a</i>	— 16-bit address value
<i>opr0_xysp</i>	— Indexed addressing postbyte code: <i>opr3,-xys</i> Predecrement X or Y or SP by 1 . . . 8 <i>opr3,+xys</i> Preincrement X or Y or SP by 1 . . . 8 <i>opr3,xys-</i> Postdecrement X or Y or SP by 1 . . . 8 <i>opr3,xys+</i> Postincrement X or Y or SP by 1 . . . 8 <i>opr5,xysp</i> 5-bit constant offset from X or Y or SP or PC <i>abd,xysp</i> Accumulator A or B or D offset from X or Y or SP or PC
<i>opr3</i>	— Any positive integer 1 . . . 8 for pre/post increment/decrement
<i>opr5</i>	— Any integer in the range -16 . . . +15
<i>opr9</i>	— Any integer in the range -256 . . . +255
<i>opr16</i>	— Any integer in the range -32,768 . . . 65,535
<i>page</i>	— 8-bit value for PPAGE, some assemblers require # symbol before this value
<i>rel8</i>	— Label of branch destination within -128 to +127 locations
<i>rel9</i>	— Label of branch destination within -256 to +255 locations
<i>rel16</i>	— Any label within 64K memory space
<i>trapnum</i>	— Any 8-bit integer in the range \$30-\$39 or \$40-\$FF
<i>xys</i>	— X or Y or SP
<i>xysp</i>	— X or Y or SP or PC

## Operators

- + — Addition
- — Subtraction
- — Logical AND
- | — Logical OR (inclusive)
- ⊕ — Logical exclusive OR
- × — Multiplication
- ÷ — Division
- $\bar{M}$  — Negation. One's complement (invert each bit of M)
- : — Concatenate  
Example: A : B means the 16-bit value formed by concatenating 8-bit accumulator A with 8-bit accumulator B.  
A is in the high-order position.
- ⇒ — Transfer  
Example: (A) ⇒ M means the content of accumulator A is transferred to memory location M.
- ↔ — Exchange  
Example: D ↔ X means exchange the contents of D with those of X.

## Address Mode Notation

- INH — Inherent; no operands in object code
- IMM — Immediate; operand in object code
- DIR — Direct; operand is the lower byte of an address from \$0000 to \$00FF
- EXT — Operand is a 16-bit address
- REL — Two's complement relative offset; for branch instructions
- IDX — Indexed (no extension bytes); includes:
  - 5-bit constant offset from X, Y, SP, or PC
  - Pre/post increment/decrement by 1 . . . 8
  - Accumulator A, B, or D offset
- IDX1 — 9-bit signed offset from X, Y, SP, or PC; 1 extension byte
- IDX2 — 16-bit signed offset from X, Y, SP, or PC; 2 extension bytes
- [IDX2] — Indexed-indirect; 16-bit offset from X, Y, SP, or PC
- [D, IDX] — Indexed-indirect; accumulator D offset from X, Y, SP, or PC

## Machine Coding

- dd — 8-bit direct address \$0000 to \$00FF. (High byte assumed to be \$00).
- ee — High-order byte of a 16-bit constant offset for indexed addressing.
- eb — Exchange/Transfer post-byte. See [Table A-5](#) on page 505.
- ff — Low-order eight bits of a 9-bit signed constant offset for indexed addressing, or low-order byte of a 16-bit constant offset for indexed addressing.
- hh — High-order byte of a 16-bit extended address.
- ii — 8-bit immediate data value.
- jj — High-order byte of a 16-bit immediate data value.
- kk — Low-order byte of a 16-bit immediate data value.
- lb — Loop primitive (DBNE) post-byte. See [Table A-6](#) on page 507.
- ll — Low-order byte of a 16-bit extended address.
- mm — 8-bit immediate mask value for bit manipulation instructions. Set bits indicate bits to be affected.
- pg — Program page (bank) number used in CALL instruction.
- qq — High-order byte of a 16-bit relative offset for long branches.
- tn — Trap number \$30–\$39 or \$40–\$FF.
- rr — Signed relative offset \$80 (–128) to \$7F (+127). Offset relative to the byte following the relative offset byte, or low-order byte of a 16-bit relative offset for long branches.
- xb — Indexed addressing post-byte. See [Table A-3](#) on page 503 and [Table A-4](#) on page 504.

## Access Detail

Each code letter except (,), and comma equals one CPU12 cycle. Uppercase = 16-bit operation and lowercase = 8-bit operation. For complex sequences see the *CPU12 Reference Manual (CPU12RM/AD)* for more detailed information.

f	— Free cycle, CPU12 doesn't use bus
g	— Read PPAGE internally
I	— Read indirect pointer (indexed indirect)
i	— Read indirect PPAGE value (CALL indirect only)
n	— Write PPAGE internally
NA	— Not available
O	— Optional program word fetch (P) if instruction is misaligned and has an odd number of bytes of object code — otherwise, appears as a free cycle (f); Page 2 prebyte treated as a separate 1-byte instruction
P	— Program word fetch (always an aligned-word read)
r	— 8-bit data read
R	— 16-bit data read
s	— 8-bit stack write
S	— 16-bit stack write
w	— 8-bit data write
W	— 16-bit data write
u	— 8-bit stack read
U	— 16-bit stack read
V	— 16-bit vector fetch (always an aligned-word read)
t	— 8-bit conditional read (or free cycle)
T	— 16-bit conditional read (or free cycle)
x	— 8-bit conditional write (or free cycle)
()	— Indicate a microcode loop
,	— Indicates where an interrupt could be honored

## Special Cases

PPP/P	— Short branch, PPP if branch taken, P if not
OPPP/OPO	— Long branch, OPPP if branch taken, OPO if not

## Condition Codes Columns

—	— Status bit not affected by operation.
0	— Status bit cleared by operation.
1	— Status bit set by operation.
Δ	— Status bit affected by operation.
fl	— Status bit may be cleared or remain set, but is not set by operation.
↑	— Status bit may be set or remain cleared, but is not cleared by operation.
?	— Status bit may be changed by operation but the final state is not defined.
!	— Status bit used for a special purpose.

REV	MIN-MAX rule evaluation Find smallest rule input (MIN). Store to rule outputs unless fuzzy output is already larger (MAX).  For rule weights see REVW.  Each rule input is an 8-bit offset from the base address in Y. Each rule output is an 8-bit offset from the base address in Y. \$FE separates rule inputs from rule outputs. \$FF terminates the rule list.  REV may be interrupted.	Special	18 3A	$Orf(t, tx)O$ (exit + re-entry replaces comma above if interrupted)  $ff + Orf(t, \quad ff + Orf(t,$	$Orf(t, tx)O$	--?-	??Δ?
REVV	MIN-MAX rule evaluation Find smallest rule input (MIN). Store to rule outputs unless fuzzy output is already larger (MAX).  Rule weights supported, optional.  Each rule input is the 16-bit address of a fuzzy input. Each rule output is the 16-bit address of a fuzzy output. The value \$FFE separates rule inputs from rule outputs. \$FFF terminates the rule list.  REVV may be interrupted.	Special	18 3B	$ORf(t, Tx)O$ (loop to read weight if enabled) $(r, RfRf)$ (exit + re-entry replaces comma above if interrupted) $ffff + ORf(t, \quad ffff + ORf(t,$	$ORf(t, Tx)O$	--?-	??Δ!

**Key to Table A-2**

\* The opcode \$04 (on sheet 1 of 3) corresponds to one of the loop primitive instructions DBEQ, DBNE, IBEQ, IBNE, TBEQ, or TBNE.

Page 2 When the CPU12 encounters a page 2 opcode (\$18 on page 1 of the opcode map), it treats the next byte of object code as a page 2 instruction opcode.

† Refer to instruction summary for more information.

§ EMUL requires 3 cycles for HCS12.

\* The opcode \$04 (on sheet 1 of 3) corresponds to one of the loop primitive instructions DBEQ, DBNE, IBEQ, IBNE, TBEQ, or TBNE.

† Refer to instruction summary for more information.

Page 2 When the CPU12 encounters a page 2 opcode (\$18 on page 1 of the opcode map), it treats the next byte of object code as a page 2 instruction opcode.

## Key to Table A-3

**Table A-4. Indexed Addressing Mode Summary**

Postbyte Code (xb)	Operand Syntax	Comments
rr0nnnnn	,r n,r -n,r	<b>5-bit constant offset</b> n = -16 to +15 rr can specify X, Y, SP, or PC
111rr0zs	n,r -n,r	<b>Constant offset</b> (9- or 16-bit signed) z=0 = 9-bit with sign in LSB of postbyte (s) 1 = 16-bit if z = s = 1, 16-bit offset indexed-indirect (see below) rr can specify X, Y, SP, or PC
rr1pnnnn	n,-r n,+r n,r- n,r+	<b>Auto predecrement, preincrement, postdecrement, or postincrement;</b> p = pre-(0) or post-(1), n = -8 to -1, +1 to +8 rr can specify X, Y, or SP (PC not a valid choice)
111rr1aa	A,r B,r D,r	<b>Accumulator offset</b> (unsigned 8-bit or 16-bit) aa -00 = A 01 = B 10 = D (16-bit) 11 = see accumulator D offset indexed-indirect rr can specify X, Y, SP, or PC
111rr011	[n,r]	<b>16-bit offset indexed-indirect</b> rr can specify X, Y, SP, or PC
111rr111	[D,r]	<b>Accumulator D offset indexed-indirect</b> rr can specify X, Y, SP, or PC

## A.5 Hexadecimal to Decimal Conversion

To convert a hexadecimal number (up to four hexadecimal digits) to decimal, look up the decimal equivalent of each hexadecimal digit in [Table A-9](#). The decimal equivalent of the original hexadecimal number is the sum of the weights found in the table for all hexadecimal digits.

**Table A-9. Hexadecimal to/from Decimal Conversion**

15Bit8				7Bit0			
1512		118		74		30	
4th Hex Digit		3rd Hex Digit		2nd Hex Digit		1st Hex Digit	
Hex	Decimal	Hex	Decimal	Hex	Decimal	Hex	Decimal
0	0	0	0	0	0	0	0
1	4,096	1	256	1	16	1	1
2	8,192	2	512	2	32	2	2
3	12,288	3	768	3	48	3	3
4	16,384	4	1,024	4	64	4	4
5	20,480	5	1,280	5	80	5	5

## A.6 Decimal to Hexadecimal Conversion

To convert a decimal number (up to  $65,535_{10}$ ) to hexadecimal, find the largest decimal number in [Table A-9](#) that is less than or equal to the number you are converting. The corresponding hexadecimal digit is the most significant hexadecimal digit of the result. Subtract the decimal number found from the original decimal number to get the *remaining decimal value*. Repeat the procedure using the remaining decimal value for each subsequent hexadecimal digit.

## Appendix B. High-Level Language Support

### B.1 Introduction

Many programmers are turning to high-level languages such as C as an alternative to coding in native assembly languages. High-level language (HLL) programming can improve productivity and produce code that is more easily maintained than assembly language programs. The most serious drawback to the use of HLL in MCUs has been the relatively large size of programs written in HLL. Larger program ROM size requirements translate into increased system costs.

Motorola solicited the cooperation of third-party software developers to assure that the CPU12 instruction set would meet the needs of a more efficient generation of compilers. Several features of the CPU12 were specifically designed to improve the efficiency of compiled HLL, and thus minimize cost.

This appendix identifies CPU12 instructions and addressing modes that provide improved support for high-level language. C language examples are provided to demonstrate how these features support efficient HLL structures and concepts. Since the CPU12 instruction set is a superset of the M68HC11 instruction set, some of the discussions use the M68HC11 as a basis for comparison.

### B.2 Data Types

The CPU12 supports the bit-sized data type with bit manipulation instructions which are available in extended, direct, and indexed variations. The char data type is a simple 8-bit value that is commonly used to specify variables in a small microcontroller system because it requires less memory space than a 16-bit integer (provided the variable has a range small enough to fit into eight bits). The 16-bit CPU12 can easily handle 16-bit integer types and the available set of conditional branches (including long branches) allow branching based on signed or

unsigned arithmetic results. Some of the higher math functions allow for division and multiplication involving 32-bit values, although it is somewhat less common to use such long values in a microcontroller system.

The CPU12 has special sign extension instructions to allow easy type-casting from smaller data types to larger ones, such as from char to integer. This sign extension is automatically performed when an 8-bit value is transferred to a 16-bit register.

### B.3 Parameters and Variables

High-level languages make extensive use of the stack, both to pass variables and for temporary and local storage. It follows that there should be easy ways to push and pull each CPU12 register, stack pointer based indexing should be allowed, and that direct arithmetic manipulation of the stack pointer value should be allowed. The CPU12 instruction set provided for all of these needs with improved indexed addressing, the addition of an LEAS instruction, and the addition of push and pull instructions for the D accumulator and the CCR.

#### B.3.1 Register Pushes and Pulls

The M68HC11 has push and pull instructions for A, B, X, and Y, but requires separate 8-bit pushes and pulls of accumulators A and B to stack or unstack the 16-bit D accumulator (the concatenated combination of A:B). The PSHD and PULD instructions allow directly stacking the D accumulator in the expected 16-bit order.

Adding PSHC and PULC improved orthogonality by completing the set of stacking instructions so that any of the CPU12 registers can be pushed or pulled. These instructions are also useful for preserving the CCR value during a function call subroutine.

### B.3.2 Allocating and Deallocating Stack Space

The LEAS instruction can be used to allocate or deallocate space on the stack for temporary variables:

```
LEAS    -10,S    ;Allocate space for 5 16-bit integers
LEAS    10,S     ;Deallocate space for 5 16-bit ints
```

The (de)allocation can even be combined with a register push or pull as in this example:

```
LDX     8,S+     ;Load return value and deallocate
```

X is loaded with the 16-bit integer value at the top of the stack, and the stack pointer is adjusted up by eight to deallocate space for eight bytes worth of temporary storage. Post-increment indexed addressing is used in this example, but all four combinations of pre/post increment/decrement are available (offsets from  $-8$  to  $+8$  inclusive, from X, Y, or SP). This form of indexing can often be used to get an index (or stack pointer) adjustment for free during an indexed operation (the instruction requires no more code space or cycles than a zero-offset indexed instruction).

### B.3.3 Frame Pointer

In the C language, it is common to have a frame pointer in addition to the CPU12 stack pointer. The frame is an area of memory within the system stack which is used for parameters and local storage of variables used within a function subroutine. The following is a description of how a frame pointer can be set up and used.

First, parameters (typically values in CPU12 registers) are pushed onto the system stack prior to using a JSR or CALL to get to the function subroutine. At the beginning of the called subroutine, the frame pointer of the calling program is pushed onto the stack. Typically, an index register, such as X, is used as the frame pointer, so a PSHX instruction would save the frame pointer from the calling program.

Next, the called subroutine establishes a new frame pointer by executing a TFR S,X. Space is allocated for local variables by executing an LEAS  $-n,S$ , where  $n$  is the number of bytes needed for local variables.

Notice that parameters are at positive offsets from the frame pointer while locals are at negative offsets. In the M68HC11, the indexed addressing mode uses only positive offsets, so the frame pointer always

points to the lowest address of any parameter or local. After the function subroutine finishes, calculations are required to restore the stack pointer to the mid-frame position between the locals and the parameters before returning to the calling program. The CPU12 only requires execution of TFR X,S to deallocate the local storage and return.

The concept of a frame pointer is supported in the CPU12 through a combination of improved indexed addressing, universal transfer/exchange, and the LEA instruction. These instructions work together to achieve more efficient handling of frame pointers. It is important to consider the complete instruction set as a complex system with subtle interrelationships rather than simply examining individual instructions when trying to improve an instruction set. Adding or removing a single instruction can have unexpected consequences.

### B.4 Increment and Decrement Operators

In C, the notation `++i` or `i--` is often used to form loop counters. Within limited constraints, the CPU12 loop primitives can be used to speed up the loop count and branch function.

The CPU12 includes a set of six basic loop control instructions which decrement, increment, or test a loop count register, and then branch if it is either equal to zero or not equal to zero. The loop count register can be A, B, D, X, Y, or SP. A or B could be used if the loop count fits in an 8-bit char variable; the other choices are all 16-bit registers. The relative offset for the loop branch is a 9-bit signed value, so these instructions can be used with loops as long as 256 bytes.

In some cases, the pre- or post-increment operation can be combined with an indexed instruction to eliminate the cost of the increment operation. This is typically done by post-compile optimization because the indexed instruction that could absorb the increment/decrement operation may not be apparent at compile time.

### B.5 Higher Math Functions

In the CPU12, subtle characteristics of higher math operations such as IDIVS and EMUL are arranged so a compiler can handle inputs and outputs more efficiently.

The most apparent case is the IDIVS instruction, which divides two 16-bit signed numbers to produce a 16-bit result. While the same function can be accomplished with the EDIVS instruction (a 32 by 16 divide), doing so is much less efficient because extra steps are required to prepare inputs to the EDIVS, and because EDIVS uses the Y index register. EDIVS uses a 32-bit signed numerator and the C compiler would typically want to use a 16-bit value (the size of an integer data type). The 16-bit C value would need to be sign-extended into the upper 16 bits of the 32-bit EDIVS numerator before the divide operation.

Operand size is also a potential problem in the extended multiply operations but the difficulty can be minimized by putting the results in CPU12 registers. Having higher precision math instructions is not necessarily a requirement for supporting high-level language because these functions can be performed as library functions. However, if an application requires these functions, the code is much more efficient if the MCU can use native instructions instead of relatively large, slow routines.

## B.6 Conditional If Constructs

In the CPU12 instruction set, most arithmetic and data manipulation instructions automatically update the condition code register, unlike other architectures that only change condition codes during a few specific compare instructions. The CPU12 includes branch instructions that perform conditional branching based on the state of the indicators in the condition codes register. Short branches use a single byte relative offset that allows branching to a destination within about  $\pm 128$  locations from the branch. Long branches use a 16-bit relative offset that allows conditional branching to any location in the 64-Kbyte map.

## B.7 Case and Switch Statements

Case and switch statements (and computed GOTOs) can use PC-relative indirect addressing to determine which path to take. Depending upon the situation, cases can use either the constant offset variation or the accumulator D offset variation of indirect indexed addressing.

### B.8 Pointers

The CPU12 supports pointers by allowing direct arithmetic operations on the 16-bit index registers (LEAS, LEAX, and LEAY instructions) and by allowing indexed indirect addressing modes.

### B.9 Function Calls

Bank switching is a fairly common way of adapting a CPU12 with a 16-bit address bus to accommodate more than 64 Kbytes of program memory space. One of the most significant drawbacks of this technique has been the requirement to mask (disable) interrupts while the bank page value was being changed. Another problem is that the physical location of the bank page register can change from one MCU derivative to another (or even due to a change to mapping controls by a user program). In these situations, an operating system program has to keep track of the physical location of the page register. The CPU12 addresses both of these problems with the uninterruptible CALL and return-from-call (RTC) instructions.

The CALL instruction is similar to a JSR instruction, except that the programmer supplies a destination page value as part of the instruction. When CALL executes, the old page value is saved on the stack and the new page value is written to the bank page register. Since the CALL instruction is uninterruptible, this eliminates the need to separately mask off interrupts during the context switch.

The CPU12 has dedicated signal lines that allow the CPU12 to access the bank page register without having to use an address in the normal 64-Kbyte address space. This eliminates the need for the program to know where the page register is physically located.

The RTC instruction is similar to the RTS instruction, except that RTC uses the byte of information that was saved on the stack by the corresponding CALL instruction to restore the bank page register to its old value. Although a CALL/RTC pair can be used to access any function subroutine regardless of the location of the called routine (on the current bank page or a different page), it is most efficient to access some subroutines with JSR/RTS instructions when the called subroutine is on the current page or in an area of memory that is always visible in the 64-Kbyte map regardless of the bank page selection.

Push and pull instructions can be used to stack some or all the CPU12 registers during a function call. The CPU12 can push and pull any of the CPU12 registers A, B, CCR, D, X, Y, or SP.

## **B.10 Instruction Set Orthogonality**

One helpful aspect of the CPU12 instruction set, orthogonality, is difficult to quantify in terms of direct benefit to an HLL compiler. Orthogonality refers to the regularity of the instruction set. A completely orthogonal instruction set would allow any instruction to operate in any addressing mode, would have identical code sizes and execution times for similar operations on different registers, and would include both signed and unsigned versions of all mathematical instructions. Greater regularity of the instruction set makes it possible to implement compilers more efficiently, because operation is more consistent, and fewer special cases must be handled.

CCR (see <i>Condition codes register</i> )	
Changes in execution flow	55–59
CLC instruction	170
Clear instructions	71
Clear memory	172, 175, 176, 177
Cleared	23
CLI instruction	171
Clock monitor reset	410
CLR instruction	172
CLRA instruction	173
CLRB instruction	174
CLRW instruction	175
CLRX instruction	176
CLRY instruction	177
CLV instruction	178
CMPA instruction	179
CMPB instruction	180
COM instruction	181
COMA instruction	182
COMB instruction	183
Compare instructions	69
Complement instructions	71
Computer operating properly (COP) watchdog	410
COMW instruction	184
COMX instruction	185
COMY instruction	186
Condition codes instructions	91, 123, 321, 326, 327, 333, 334, 382, 389
Condition codes register	25, 28–33
C status bit	33, 74, 139, 141
H status bit	31, 195
I mask bit	32, 123, 171, 365, 401, 408, 411
Manipulation	91, 123, 321, 365
N status bit	32
S control bit	371
V status bit	33
X mask bit	30, 221, 333, 334, 356, 371, 382, 387, 401, 408, 410, 411

Z status bit	32, 142, 157
Conditional 16-bit read cycle	106, 478
Conditional 8-bit read cycle	106, 478
Conditional 8-bit write cycle	106, 478
Conserving power	92, 371, 401
Constant indirect indexed addressing mode	44
Constant offset indexed addressing mode	43, 44
COP reset	410
CPCD instruction	188
CPCS instruction	189
CPCX instruction	190
CPCY instruction	191
CPD instruction	187
CPS instruction	192
CPX instruction	193
CPY instruction	194
Cycle code letters	102, 478
Cycle-by-cycle operation	102, 478

## D

DAA instruction	195
DATA mnemonic	23
Data types	33, 511
DBEQ instruction	196, 507
DBNE instruction	197, 507
DEC instruction	198
DECA instruction	199
DECB instruction	200
Decrement instructions	68
DECW instruction	201
DECX instruction	202
DECY instruction	203
Defuzzification	440, 461–464
DES instruction	204
DEX instruction	205
DEY instruction	206
Direct addressing mode	38
Division instructions	72, 514
16-bit fractional	223
16-bit integer	238, 239
32-bit extended	207, 208
Double accumulator	25, 27

## E

EDIV instruction	207
EDIVS instruction	208
Effective address	35, 41, 90, 275, 276, 277, 512–514
EMACS instruction	78, 209
EMAXD instruction	210
EMAXM instruction	211, 434
EMIND instruction	212, 433
EMINM instruction	213
EMUL instruction	214
EMULS instruction	215
Enabling maskable interrupts	32, 171
EORA instruction	216
EORB instruction	217, 229
EORX instruction	218
EORY instruction	219
ETBL instruction	79, 220, 434
Even bytes	34
Exceptions	55, 405
Interrupts	410
Maskable interrupts	411, 412
Non-maskable interrupts	410
Priority	407
Processing flow	414
Resets	405, 409–410
Software interrupts	86, 380, 414
Unimplemented opcode trap	405, 408, 413
Vectors	405, 414
Exchange instructions	63, 221, 222
Postbyte encoding	505
Execution cycles	102
Execution time	102
EXG instruction	221, 222
Expanded memory	50, 56, 516
Bank switching	50
Instructions	50, 85, 168, 355
Page registers	50
Subroutines	85, 516
Extended addressing mode	39
Extended division	72
Extension byte	41
External interrupts	412

External queue reconstruction .....	419
HCS12 queue reconstruction .....	425
HCS12 reconstruction algorithm .....	427
HCS12 timing detail .....	421, 423
External reset .....	409

## F

f-cycle (free cycle) .....	102, 478
FDIV instruction .....	72, 223
Fractional division .....	72, 223
Frame pointer .....	513, 514
Free cycle .....	102, 478
Fuzzy logic .....	433–472
Antecedents .....	438, 470
Consequents .....	439, 470
Custom programming .....	467
Defuzzification .....	76, 440, 461–466
Fuzzification .....	75, 436, 467
Inference kernel .....	435, 441
Inputs .....	470
Instructions .....	75, 76, 294, 338–342, 402, 433, 444–466
Interrupts .....	458, 462–464
Knowledge base .....	435, 439, 470
Membership functions .....	75, 294, 434, 435, 436, 444–449, 467–469
Outputs .....	76, 470
Rule evaluation .....	75, 338–342, 438, 450–461, 470
Rules .....	436, 438, 470
Sets .....	435
Tabular membership functions .....	79, 467
Weighted average .....	76, 402, 433, 440, 461–466

## G

g-cycle (read PPAGE) .....	103, 478
General purpose accumulators .....	25
GLDAA instruction .....	224
GLDAB instruction .....	225
GLDD instruction .....	226
GLDS instruction .....	227
GLDX instruction .....	228
Global interrupt mask .....	32, 408
GSTAA instruction .....	230

GSTAB instruction .....	231
GSTD instruction .....	232
GSTS instruction .....	233
GSTX instruction .....	234
GSTY instruction .....	235

## H

H status bit .....	31, 195
Highest priority interrupt .....	408
High-level language .....	511–517
Addressing modes .....	511, 513, 515
Condition codes register .....	515
Expanded memory .....	516
Instructions .....	511
Loop primitives .....	514
Stack .....	512, 513

## I

I mask bit .....	32, 123, 171, 365, 408
IBEQ instruction .....	236, 507
IBNE instruction .....	237, 507
I-cycle (16-bit read indirect) .....	103, 478
i-cycle (8-bit read indirect) .....	103, 478
IDIV instruction .....	238
IDIVS instruction .....	239, 514
Immediate addressing mode .....	37
INC instruction .....	240
INCA instruction .....	241
INCB instruction .....	242
Increment instructions .....	68
INCW instruction .....	243
INCX instruction .....	244
INCY instruction .....	245
Index calculation instructions .....	90
Index manipulation instructions .....	88
Index registers .....	25, 88, 90, 513
PC (as an index register) .....	28, 42, 43, 102
SP (as an index register) .....	27, 42, 43, 102
X .....	27, 42, 43, 102
Y .....	27, 42, 43, 102
Indexed addressing modes .....	27, 40–50, 503

16-bit constant indirect .....	44
16-bit constant offset .....	44
5-bit constant offset .....	43
9-bit constant offset .....	43
Accumulator direct .....	47
Accumulator offset .....	46
Auto increment/decrement indexing .....	45
Base index register .....	43–47
Extension byte .....	41
Limitations for BIT and MOV instructions	140, 160, 162, 163, 165, 297, 298, 300, 301, 302, 303, 305, 306, 307, 308, 309, 310
Postbyte .....	43
Postbyte encoding .....	41, 503
Inference kernel, fuzzy logic .....	441
Inherent addressing mode .....	36
INS instruction .....	246
Instruction pipe, see <i>Instruction queue</i>	
Instruction queue .....	34, 53, 419
Data movement .....	54
Debugging .....	419
Reconstruction .....	419–??
Status registers .....	427
Status signals .....	54, 420–??
Instruction set .....	61, 95, 479
Integer division .....	72, 238–239
Interrupt instructions .....	86
Interrupts .....	410–416
Enabling and disabling .....	30, 32, 171, 365, 411
External .....	412
I mask bit .....	32, 171, 365, 412
Instructions .....	86, 87, 171, 356, 365, 380, 390
Low-power stop .....	92, 371
Maskable .....	32, 411
Non-maskable .....	30, 405–408, 410, 411
Recognition .....	411
Return .....	30, 32, 87, 356, 413
Service routines .....	412
Software .....	86, 380, 414
Stacking order .....	412
Vectors .....	405, 413, 414
Wait instruction .....	92, 401
X mask bit .....	30, 371, 401, 412
INX instruction .....	247

INY instruction ..... 248

## J

JMP instruction ..... 59, 249  
 JSR instruction ..... 56, 250  
 Jump instructions ..... 59, 85

## K

Knowledge base ..... 435

## L

Label ..... 99  
 LBCC instruction ..... 251  
 LBCCS instruction ..... 252  
 LBEQ instruction ..... 253  
 LBGE instruction ..... 254  
 LBGT instruction ..... 255  
 LBHI instruction ..... 256  
 LBHS instruction ..... 257  
 LBLE instruction ..... 258  
 LBLO instruction ..... 259  
 LBLS instruction ..... 260  
 LBLT instruction ..... 261  
 LBMI instruction ..... 262  
 LBNE instruction ..... 263  
 LBPL instruction ..... 264  
 LBRA instruction ..... 265  
 LBRN instruction ..... 266  
 LBVC instruction ..... 267  
 LBVS instruction ..... 268  
 LDAA instruction ..... 269  
 LDAB instruction ..... 270  
 LDD instruction ..... 271  
 LDS instruction ..... 272  
 LDX instruction ..... 273  
 LDY instruction ..... 274  
 LEAS instruction ..... 275, 513, 516  
 Least significant byte ..... 23  
 Least significant word ..... 23  
 LEAX instruction ..... 276, 516

LEAY instruction	277, 516
Legal label	99
Literal expression	99
Load instructions	62
Logic level one	23
Logic level zero	23
Loop primitive instructions	58, 84, 507, 514
Offset values	84
Postbyte encoding	507
Low-power stop	92, 371
LSL instruction	74, 278
LSLA instruction	279
LSLB instruction	280
LSLD instruction	281
LSR instruction	285
LSRA instruction	286
LSRB instruction	287
LSRD instruction	288
LSRW instruction	289
LSRX instruction	290
LSRY instruction	291

## M

M68HC11 compatibility	35
Maskable interrupts	32, 411
MAXA instruction	292
Maximum instructions	78
16-bit	210, 211
8-bit	292, 293
MAXM instruction	293, 433
MEM instruction	75, 294, 433, 444–449
Membership functions	435, 444–449
Memory and addressing symbols	21
MINA instruction	295, 433
Minimum instructions	78
16-bit	212, 213
8-bit	295, 296
MINM instruction	296
Misaligned instructions	58
Mnemonic	95
Most significant byte	23
Most significant word	23

MOVB instruction .....	297, 298, 299, 300, 301, 302, 303
Move instructions	65, 297, 298, 299, 300, 301, 302, 303, 304, 305, 306, 307, 308, 309, 310
Destination .....	48
Multiple addressing modes .....	48
PC relative addressing .....	48
Reference index register .....	48
Source .....	48
MOVW instruction .....	304, 305, 306, 307, 308, 309, 310
MUL instruction .....	311
Multiple addressing modes	
Bit manipulation instructions .....	49
Move instructions .....	48
Multiplication instructions .....	72
16-bit .....	214, 215
8-bit .....	311
Multiply and accumulate instructions .....	78, 209, 402, 471

## N

N status bit .....	32
n-cycle (write PPAGE) .....	103, 478
NEG instruction .....	312
NEGA instruction .....	313
Negate instructions .....	71
Negated .....	23
Negative integers .....	33
NEGB instruction .....	314
NEGW instruction .....	315
NEGX instruction .....	316
NEGY instruction .....	317
Non-maskable interrupts .....	30, 408, 410
NOP instruction .....	93, 318
Notation	
Branch taken/not taken .....	107, 478
Changes in CCR bits .....	97
Cycle-by-cycle operation .....	102
Memory and addressing .....	21
Object code .....	98
Operators .....	22, 476
Source forms .....	99
System resources .....	20
Null operation instruction .....	93, 318

Numeric range of branch offsets .....40, 81–84

## O

Object code notation ..... 98  
 O-cycle (optional program word fetch) .....58, 104, 478  
 Odd bytes ..... 34  
 Offset  
     Branch ..... 39–40  
     Index ..... 40–45  
 Opcode map ..... 500, ??–501, ??–502  
 Operators ..... 22, 476  
 Optional cycles ..... 58, 104, 478  
 ORAA instruction ..... 319  
 ORAB instruction ..... 320  
 ORCC instruction ..... 321  
 Orthogonality ..... 517  
 ORX instruction ..... 322  
 ORY instruction ..... 323

## P

Page 2 prebyte .....57, 104, 500, 501, 502  
 P-cycle (program word fetch) ..... 104, 478  
 Pipeline ..... 34  
 Pointer calculation instructions .....90, 275, 276, 277  
 Pointers ..... 516  
 Postbyte encoding  
     Exchange instructions ..... 221, 222, 505  
     Indexed addressing instructions ..... 42  
     Indexed addressing modes ..... 43, 503  
     Loop primitive instructions ..... 507  
     Transfer instructions ..... 367, 387, 505  
 Post-decrement indexed addressing mode ..... 45  
 Post-increment indexed addressing mode ..... 45  
 Power conservation ..... 92, 371, 401  
 Power-on reset ..... 409  
 Prebyte .....57, 104, 500, 501, 502  
 Pre-decrement indexed addressing mode ..... 45  
 Pre-increment indexed addressing mode ..... 45  
 Priority, exception ..... 407  
 Program counter .....25, 28, 41, 144  
 Program word access cycle ..... 104, 478

Programming model .....	19, 25
Pseudo-non-maskable interrupt .....	408
PSHA instruction .....	324
PSHB instruction .....	325
PSHC instruction .....	326
PSHCW instruction .....	327
PSHD instruction .....	328, 512
PSHX instruction .....	329
PSHY instruction .....	330
PULA instruction .....	331
PULB instruction .....	332
PULC instruction .....	333, 512
PULCW instruction .....	334
PULD instruction .....	335, 512
Pull instructions .....	517
PULX instruction .....	336
PULY instruction .....	337
Push instructions .....	517

## Q

Queue reconstruction .....	419
HCS12 queue reconstruction .....	425
HCS12 reconstruction algorithm .....	427
HCS12 timing detail .....	421, 423

## R

R-cycle (16-bit data read) .....	105, 478
r-cycle (8-bit data read) .....	104, 478
Read 16-bit data cycle .....	105, 478
Read 8-bit data cycle .....	104, 478
Read indirect pointer cycle .....	103, 478
Read indirect PPAGE value cycle .....	103, 478
Read PPAGE cycle .....	103, 478
Register designators .....	99
Relative addressing mode .....	39
Relative offset .....	39
Resets .....	405, 409
Clock monitor .....	410
COP .....	410
External .....	409
Power-on .....	409

Return from call	355
Return from interrupt	356
Return from subroutine	357
REV instruction	75, 338–339, 433, 438, 450–455, 470
REW instruction	75, 340–342, 433, 438, 456–461, 470
ROL instruction	343
ROLA instruction	344
ROLB instruction	345
ROLW instruction	346
ROLX instruction	347
ROLY instruction	348
ROR instruction	349
RORA instruction	350
RORB instruction	351
RORW instruction	352
RORX instruction	353
RORY instruction	354
Rotate instructions	74
RTC instruction	50, 56, 85, 355, 516
RTI instruction	32, 87, 356, 413
RTS instruction	56, 357

## S

S control bit	371
SBA instruction	358
SBCA instruction	359
SBCB instruction	360
SBED instruction	361
SBEX instruction	362
SBEY instruction	363
S-cycle (16-bit stack write)	105, 478
s-cycle (8-bit stack write)	105, 478
SEC instruction	364
SEI instruction	365
Service routine	406
Set	23
Setting memory bits	163, 165
SEV instruction	366
SEX instruction	63, 367
Shift instructions	74
Arithmetic	133, 136, 137, 138
Sign extension instruction	63, 367, 512

Signed branches .....	80–82
Signed integers .....	33
Signed multiplication .....	72
Simple branches .....	80–82
Software interrupts .....	380
Source code compatibility .....	19
Source form notation .....	99
STAA instruction .....	368
STAB instruction .....	369
Stack .....	27
Stack 16-bit data cycle .....	105, 478
Stack 8-bit data cycle .....	105, 478
Stack operation instructions .....	89
Stack pointer .....	25, 27, 41, 512
Initialization .....	27
Manipulation .....	89
Stacking order .....	412
Stack pointer instructions .....	89, 512
Standard CPU12 address space .....	34
STD instruction .....	370
STOP continue .....	371
STOP disable .....	30, 371
STOP instruction .....	92, 371
Store instructions .....	62
STS instruction .....	372
STX instruction .....	373
STY instruction .....	374
SUBA instruction .....	375
SUBB instruction .....	376
SUBD instruction .....	377
Subroutine instructions .....	85
Subroutines .....	56, 516
Expanded memory .....	56, 85, 168, 355, 516
Instructions .....	85, 164, 168, 250, 516
Return .....	355, 357
Subtraction instructions .....	66
SUBX instruction .....	378
SUBY instruction .....	379
SWI instruction .....	86, 380, 414
Switch statements .....	515
Symbols and notation .....	20, 475

## T

TAB instruction .....	381
Table interpolation instructions .....	79, 220, 385
Tabular membership functions .....	467–469
TAP instruction .....	382
TBA instruction .....	383
TBEQ instruction .....	384, 507
TBL instruction .....	79, 385, 434, 467–468
TBNE instruction .....	386, 507
T-cycle (16-bit conditional read) .....	106, 478
t-cycle (8-bit conditional read) .....	106, 478
Termination of interrupt service routines .....	87, 356, 413
Termination of subroutines .....	355, 357
Test instructions .....	69
TFR instruction .....	387, 388
TPA instruction .....	389
Transfer instructions .....	63
Postbyte encoding .....	505
TRAP instruction .....	87, 390, 413, 501
TST instruction .....	391
TSTA instruction .....	392
TSTB instruction .....	393
TSTW instruction .....	394
TSTX instruction .....	395
TSTY instruction .....	396
TSX instruction .....	397
TSY instruction .....	398
Twos-complement form .....	33
TXS instruction .....	399
Types of instructions	
Addition and Subtraction .....	66
Background and null .....	93
Binary-coded decimal .....	67
Bit test and manipulation .....	73
Boolean logic .....	70
Branch .....	80
Clear, complement, and negate .....	71
Compare and test .....	69
Condition code .....	91
Decrement and increment .....	68
Fuzzy logic .....	75
Index manipulation .....	88

Interrupt .....	86–87
Jump and subroutine .....	85
Load and store .....	62
Loop primitives .....	84
Maximum and minimum .....	78
Move .....	65
Multiplication and division .....	72
Multiply and accumulate .....	78
Pointer and index calculation .....	90
Shift and rotate .....	74
Sign extension .....	63
Stacking .....	89
Stop and wait .....	92
Table interpolation .....	79
Transfer and exchange .....	63
TYS instruction .....	400

## U

U-cycle (16-bit stack read) .....	106, 478
u-cycle (8-bit stack read) .....	105, 478
Unary branches .....	80–82
Unimplemented opcode trap .....	87, 390, 405, 408, 501
Unsigned branches .....	80–82
Unsigned multiplication .....	72
Unstack 16-bit data cycle .....	106, 478
Unstack 8-bit data cycle .....	105, 478
Unweighted rule evaluation .....	338–339, 438, 450–455, 470

## V

V status bit .....	33, 91
V-cycle (vector fetch) .....	106, 478
Vector fetch cycle .....	106, 478
Vectors, exception .....	405, 414

## W

WAI instruction .....	92, 401
Wait instruction .....	92, 401
Watchdog .....	410
WAV instruction .....	76, 402, 433, 440, 461–464
HCS12 .....	465

M68HC12 .....	466
wavr pseudo-instruction .....	462–464
HCS12 .....	465
M68HC12 .....	466
W-cycle (16-bit data write) .....	105, 478
w-cycle (8-bit data write) .....	105, 478
Weighted average .....	402
Weighted rule evaluation .....	340–342, 438, 450–452, 456–461, 470
Word moves .....	65, 304, 305, 306, 307, 308, 309, 310
Write 16-bit data cycle .....	105, 478
Write 8-bit data cycle .....	105, 478
Write PPAGE cycle .....	103, 478

## X

X mask bit .....	30, 221, 333, 334, 356, 371, 382, 387, 401
x-cycle (8-bit conditional write) .....	106, 478
XGDX instruction .....	403
XGDY instruction .....	404

## Z

Z status bit .....	32, 142, 157
Zero-page addressing .....	38

Information in this document is provided solely to enable system and software implementers to use Motorola products. There are no express or implied copyright licenses granted hereunder to design or fabricate any integrated circuits or integrated circuits based on the information in this document.

Motorola reserves the right to make changes without further notice to any products herein. Motorola makes no warranty, representation or guarantee regarding the suitability of its products for any particular purpose, nor does Motorola assume any liability arising out of the application or use of any product or circuit, and specifically disclaims any and all liability, including without limitation consequential or incidental damages. "Typical" parameters that may be provided in Motorola data sheets and/or specifications can and do vary in different applications and actual performance may vary over time. All operating parameters, including "Typicals", must be validated for each customer application by customer's technical experts. Motorola does not convey any license under its patent rights nor the rights of others. Motorola products are not designed, intended, or authorized for use as components in systems intended for surgical implant into the body, or other applications intended to support or sustain life, or for any other application in which the failure of the Motorola product could create a situation where personal injury or death may occur. Should Buyer purchase or use Motorola products for any such unintended or unauthorized application, Buyer shall indemnify and hold Motorola and its officers, employees, subsidiaries, affiliates, and distributors harmless against all claims, costs, damages, and expenses, and reasonable attorney fees arising out of, directly or indirectly, any claim of personal injury or death associated with such unintended or unauthorized use, even if such claim alleges that Motorola was negligent regarding the design or manufacture of the part.

MOTOROLA and the Stylized M Logo are registered in the US Patent and Trademark Office. All other product or service names are the property of their respective owners. Motorola, Inc. is an Equal Opportunity/Affirmative Action Employer.
