## SECTION 1 GENERAL DESCRIPTION

The MC68HC05C12 is a member of the low-cost, high-performance M68HC05 Family of 8-bit microcontroller units (MCUs). The M68HC05 Family is based on the customer-specified integrated circuit (CSIC) design strategy. All MCUs in the family use the M68HC05 central processor unit (CPU) and are available with a variety of subsystems, memory sizes and types, and package types.

**Appendix A** introduces the MC68HCL05C12, a low-power version of the MC68HC05C12. **Appendix B** introduces the MC68HSC05C12, a high-speed version of the MC68HC05C12.

On-chip memory of the MC68HC05C12 includes 12096 bytes of user ROM and 176 bytes of on-chip RAM.

### 1.1 Features

Features of the MCU include the following:

- HC05 CPU
- 12096 Bytes of User ROM
- 176 Bytes of On-Chip RAM
- Compatible with MC68HC05C4/C8/C9 MCUs
- Memory Mapped Input/Output (I/O)
- On-Chip Oscillator with Resistor-Capacitor (RC) or Crystal/Ceramic Resonator Mask Options
- Asynchronous Serial Communications Interface (SCI) Subsystem
- Synchronous Serial Peripheral Interface (SPI) Subsystem
- 16-Bit Capture/Compare Timer Subsystem
- Computer Operating Properly (COP) Watchdog Timer
- 24 Bidirectional I/O Lines Plus One Fixed Input Port
- Power Saving STOP and WAIT Modes
- Single 3.0- to 5.5-Volt Power Supply Requirement
- Self-Check Mode
- Edge-Sensitive or Edge- & Level-Sensitive Interrupt Trigger Mask Option
- High Current Sink and Source on One Port Pin (PC7)
- Mask Optional Interrupt Capability (Pullups) for each of the 8 Port B Pins
- 40-Pin Dual-In-Line Package (DIP)
- 44-Pin Plastic-Leaded Chip Carrier (PLCC)
- 44-Pin Quad Flat Pack (QFP) Package
- 42-Pin Shrink DIP (SDIP) Package

## 1.2 Mask Options

The following MC68HC05C12 mask options are available:

- Edge-sensitive only or edge- and level-sensitive external interrupt pin ( $\overline{\text{IRQ}}$  pin)
- Crystal/ceramic resonator oscillator or resistor/capacitor (RC) oscillator (default is crystal)
- STOP mode
- Port B pullup and interrupt capability for each of the Port B pins (PB7–PB0)
- COP enable/disable

### 1.3 Block Diagram

Figure 1-1 shows the structure of the MC68HC05C12 MCU.

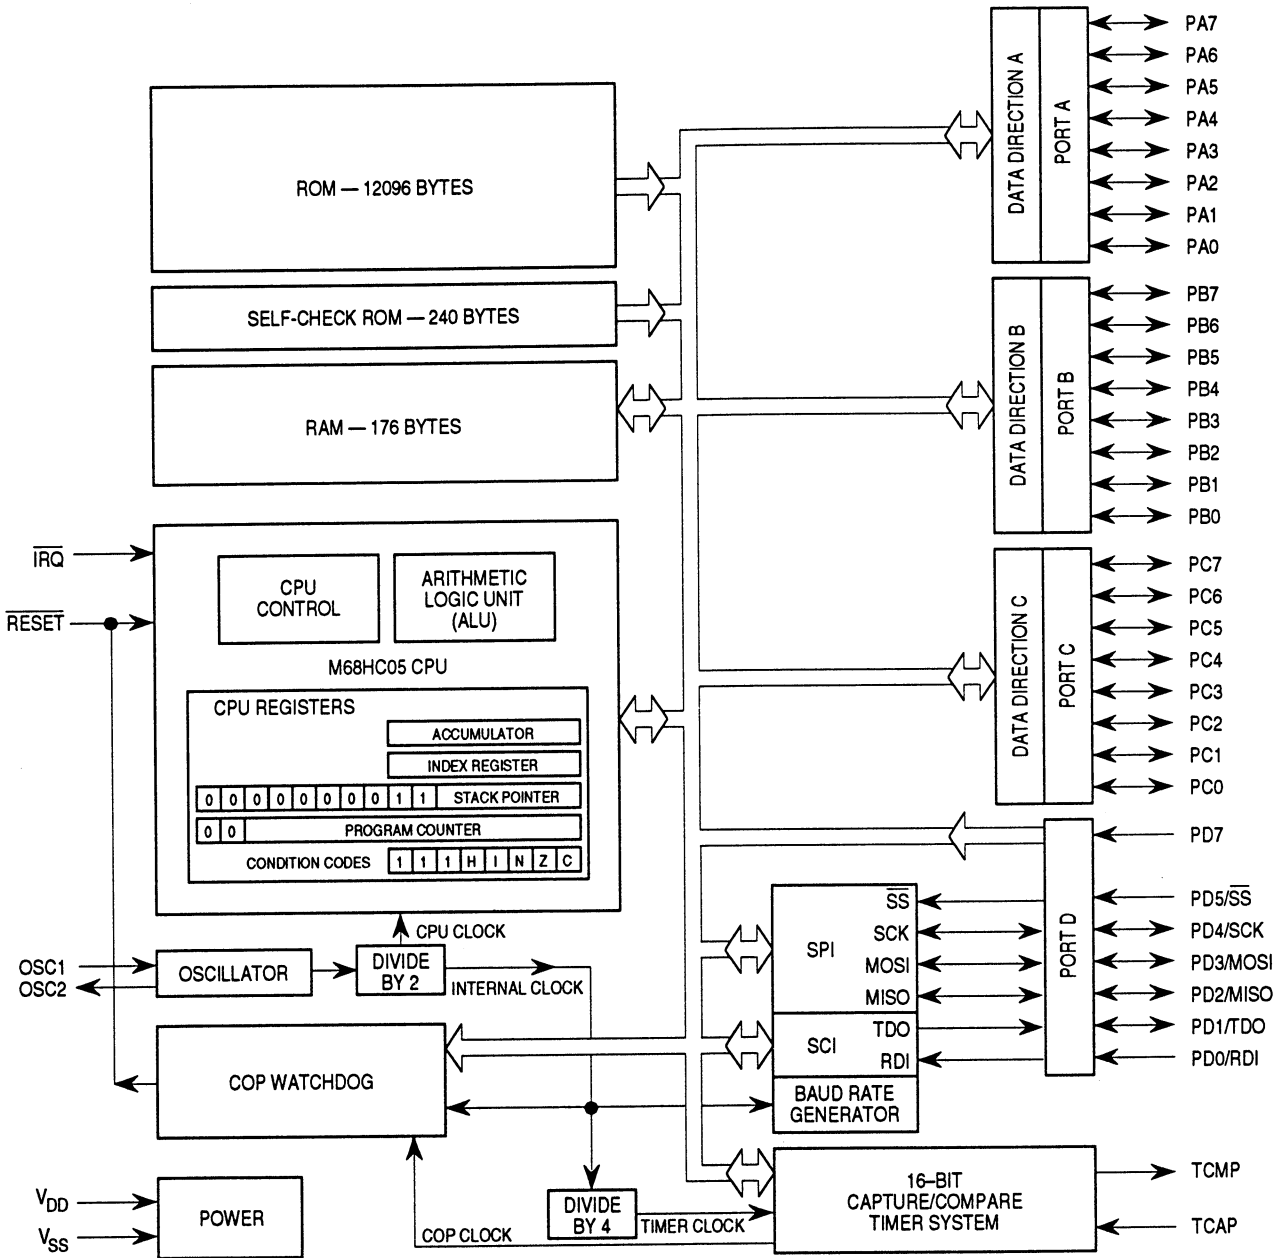

Figure 1-1. MC68HC05C12 Block Diagram

**1.4 Pin Assignments**

Figure 1-2 shows the pin assignments.

**40-Pin DIP**

**44-Pin PLCC**

**Figure 1-2. Pin Assignments (1 of 2)**

44-Pin QFP

42-Pin SDIP

Figure 1-2. Pin Assignments (2 of 2)

### 1.4.1 V<sub>DD</sub> and V<sub>SS</sub>

V<sub>DD</sub> and V<sub>SS</sub> are the power supply and ground pins. The MCU operates from a single 5-V power supply.

Very fast signal transitions occur on the MCU pins. The short rise and fall times place very high short-duration current demands on the power supply. To prevent noise problems, take special care to provide good power supply bypassing at the MCU. Use bypass capacitors with good high-frequency characteristics, and position them as close to the MCU as possible, as Figure 1-3 shows. C2 is an optional bulk current bypass capacitor for use in applications that require the port pins to source high current levels. Bypassing requirements vary, depending on how heavily loaded the MCU pins are.

Figure 1-3. Bypassing Layout Recommendation

### 1.4.2 OSC1 and OSC2

The OSC1 and OSC2 pins are the control connections for the on-chip oscillator. The oscillator can be driven by any of the following:

- Crystal resonator (Figure 1-4)
- Ceramic resonator (Figure 1-5)
- External clock signal (Figure 1-6)
- Resistor-capacitor (RC) combination (Figure 1-7)

A mask option selects either a crystal/ceramic resonator or a resistor-capacitor as the frequency-determining element. The MCU divides the frequency of the oscillator,  $f_{OSC}$ , or external clock source by two to produce the internal operating frequency,  $f_{OP}$ .

### 1.4.2.1 Crystal Resonator Mask Option

A crystal connected to the OSC1 and OSC2 pins can drive the on-chip oscillator. The circuit in Figure 1-4 shows a typical crystal oscillator circuit for an AT-cut, parallel resonant crystal. Follow the crystal supplier's recommendations, as the crystal parameters determine the external component values required to provide maximum stability and reliable startup. The load capacitance values used in the oscillator circuit design should include all stray layout capacitances. Mount the crystal and components as close as possible to the pins for startup stabilization and to minimize output distortion.

#### NOTE

Use an AT-cut crystal and not an AT-strip crystal. The MCU may overdrive an AT-strip crystal.

Figure 1-4. Crystal Resonator Connections

### 1.4.2.2 Ceramic Resonator Mask Option

In cost-sensitive applications, use a ceramic resonator in place of the crystal. Use the circuit in Figure 1-5 for a ceramic resonator, and follow the resonator manufacturer's recommendations, as the resonator parameters determine the external component values required for maximum stability and reliable starting. The load capacitance values used in the oscillator circuit design should include all stray layout capacitances.

Figure 1-5. Ceramic Resonator Connections

### 1.4.2.3 External Clock

The crystal/ceramic resonator mask option also allows for an external clock from another CMOS-compatible device to drive the OSC1 input, with the OSC2 pin not connected, as Figure 1-6 shows.

Figure 1-6. External Clock Connection

### 1.4.2.4 RC Oscillator Mask Option

With the RC oscillator option, a resistor is connected to the oscillator pins as shown in Figure 1-7. The relationship between R and  $f_{OSC}$  is shown in Figure 1-8. Consult factory for tolerance limits and design specifications.

NOTE: The accuracy of the RC oscillator mask option is limited to  $\pm 50\%$  of the chosen operating frequency.

Figure 1-7. RC Oscillator Connections

Figure 1-8. Typical RC Oscillator Frequency vs Resistance ( $V_{DD} = 5.0 \text{ V}$ ,  $25^\circ\text{C}$ )

### 1.4.3 $\overline{\text{RESET}}$

A logic zero on the RESET pin forces the MCU to a known startup state. The  $\overline{\text{RESET}}$  pin contains an internal Schmitt trigger as part of its input to improve noise immunity. (See **5.1.2 External Reset** for more information.)

### 1.4.4 $\overline{\text{IRQ}}$ (External Interrupt Request)

The  $\overline{\text{IRQ}}$  pin is used for the application of asynchronous external interrupt signals. (See **4.1.2 External Interrupt** for more information.) The  $\overline{\text{IRQ}}$  pin contains an internal Schmitt trigger as part of its input to improve noise immunity.

### 1.4.5 TCAP (Timer Capture)

This pin controls the input capture feature for the on-chip capture/compare timer. The TCAP pin contains an internal Schmitt trigger as part of its input to improve noise immunity. (See **SECTION 8 CAPTURE/COMPARE TIMER.**)

### 1.4.6 TCMP (Timer Compare)

This pin is the output for the output compare feature of the on-chip capture/compare timer. (See **SECTION 8 CAPTURE/COMPARE TIMER.**)

### 1.4.7 PA7–PA0

These eight I/O lines comprise port A. The pins are programmable as either inputs or outputs under software control of the data direction registers and are configured as inputs during power-on reset (POR) or reset. (See **7.2 Port A** for more information on Port A and **SECTION 7 PARALLEL I/O** for a description of I/O programming.)

### 1.4.8 PB7–PB0

These eight I/O lines comprise port B. The pins are programmable as either inputs or outputs under software control of the data direction registers and are configured as inputs during power-on reset (POR) or reset. Port B pins have mask-option-enabled pullup devices and interrupt capability by pin. (See **7.3 Port B** for more information on Port B and **SECTION 7 PARALLEL I/O** for a description of I/O programming.)

#### 1.4.9 PC7–PC0

These eight I/O lines comprise port C. The pins are programmable as either inputs or outputs under software control of the data direction registers and are configured as inputs during power-on reset (POR) or reset. PC7 has high current sink and source capability. (See **7.4 Port C** for more information on Port C and **SECTION 7 PARALLEL I/O** for a description of I/O programming.)

#### 1.4.10 PD7 and PD5–PD0

These seven port lines comprise port D. PD7, PD5, and PD0 are input-only pins. (See **7.5 Port D** for more information on Port D and **SECTION 7 PARALLEL I/O** for a description of I/O programming.)

The states of PD4–PD1 are software programmable and are configured as input during power-on reset (POR) or reset.

PD1 and PD0 are shared with the SCI subsystem. (See **SECTION 9 SERIAL COMMUNICATIONS INTERFACE**.)

PD5–PD2 are shared with the SPI subsystem. (See **10.2.1 Pin Functions in Master Mode** and **10.2.2 Pin Functions in Slave Mode**.)

## SECTION 2 MEMORY

Section 2 describes the organization of the on-chip memory.

### 2.1 Memory Map

The CPU can address 16 Kbytes of memory space. The ROM portion of memory holds the program instructions, fixed data, user-defined vectors, and service routines. The RAM portion of memory holds variable data. I/O registers are memory-mapped so that the CPU can access their locations in the same way that it accesses all other memory locations.

Figure 2-1 is a memory map of the MCU. Refer to Figure 2-2 for a more detailed memory map of the 32-byte I/O register section.

### 2.2 Input/Output Section

The first 32 addresses of the memory space, \$0000–\$001F, are the I/O section. These are the addresses of the I/O control registers, status registers, and data registers.

### 2.3 RAM

The MCU has 176 bytes of fully static read/write memory for storage of variable and temporary data during program execution. For the stack, the CPU uses the top 64 RAM addresses, \$00C0–\$00FF. Before processing an interrupt, the CPU uses 5 bytes of the stack to save the contents of the CPU registers. During a subroutine call, the CPU uses 2 bytes of the stack to store the return address. The stack pointer decrements during pushes and increments during pulls.

### NOTE

Be careful when using nested subroutines or multiple interrupt levels. The CPU may overwrite data in the RAM during a subroutine or during the interrupt stacking operation.

Figure 2-2. I/O Registers and Control Bits

**NOTE**

Be careful when using the stack addresses (\$00C0–\$00FF) for data storage or as a temporary work area. The CPU may overwrite data in the stack during a subroutine or interrupt.

**2.4 ROM**

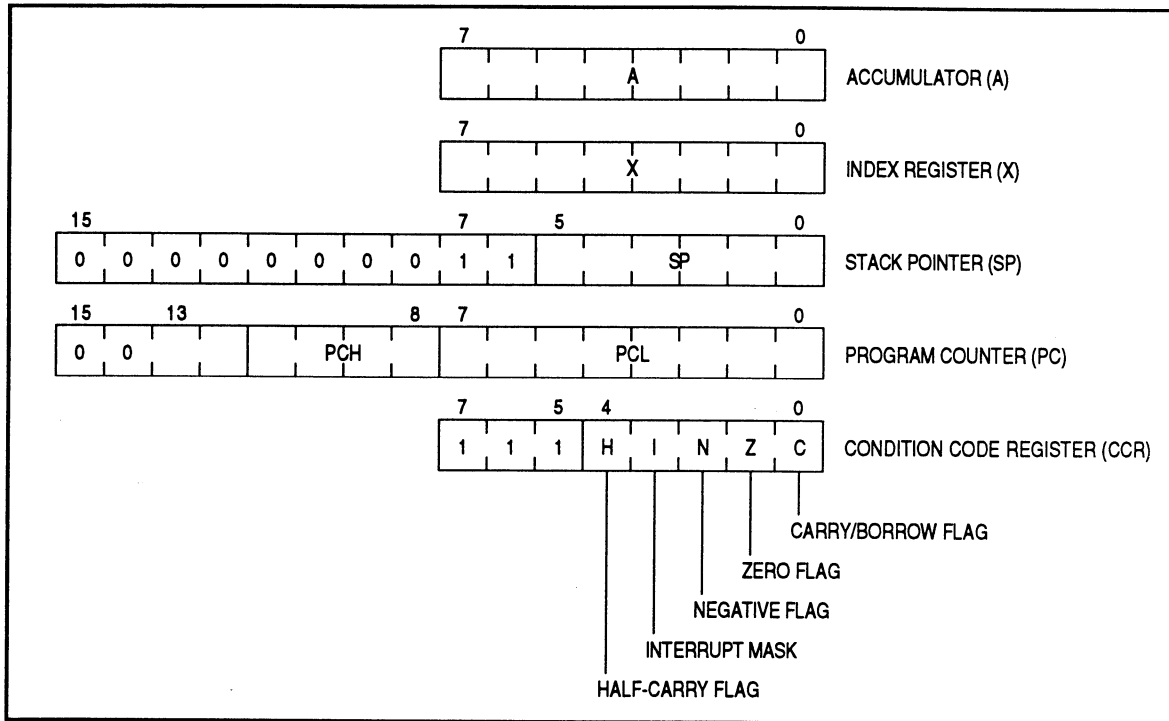

The on-chip user ROM consists of 48 bytes at addresses \$0020–\$004F, 12032 bytes at \$1000–\$3EFF, and 16 bytes of user vectors at \$3FF0–\$3FFF. Twelve of the user vectors, \$3FF4–\$3FFF, contain user-defined vectors for servicing interrupts and resets.

## SECTION 3 CENTRAL PROCESSOR UNIT

This section describes the CPU registers.

### 3.1 CPU Registers

Figure 3-1 shows the five CPU registers. These are hard-wired registers within the CPU and are not part of the memory map.

**Figure 3-1. CPU Programming Model**

### 3.1.1 Accumulator (A)

The accumulator shown in Figure 3-2 is a general-purpose 8-bit register. The CPU uses the accumulator to hold operands and results of arithmetic and nonarithmetic operations.

**Figure 3-2. Accumulator (A)**

### 3.1.2 Index Register (X)

In the indexed addressing modes, the CPU uses the byte in the index register to determine the conditional address of the operand. (See **12.1.5 Indexed, No Offset**; **12.1.6 Indexed, 8-Bit Offset**; and **12.1.7 Indexed, 16-Bit Offset**.)

**Figure 3-3. Index Register (X)**

The 8-bit index register can also serve as a temporary data storage location.

### 3.1.3 Stack Pointer (SP)

The stack pointer, shown in Figure 3-4, is a 16-bit register that contains the address of the next free location on the stack. During a reset or after the reset stack pointer (RSP) instruction, the stack pointer contents are preset to \$00FF. The address in the stack pointer decrements as data is pushed onto the stack and increments as data is pulled from the stack.

**Figure 3-4. Stack Pointer (SP)**

The ten most significant bits of the stack pointer are permanently fixed at 0000000011, and so the stack pointer produces addresses from \$00C0 to \$00FF. If subroutines and interrupts use more than 64 stack locations, the stack pointer wraps around to address \$00FF and begins writing over the previously stored data. A subroutine uses two stack locations; an interrupt uses five locations.

### 3.1.4 Program Counter (PC)

The program counter, shown in Figure 3-5, is a 16-bit register that contains the address of the next instruction or operand to be fetched. The two most significant bits of the program counter are permanently fixed at 00.

Normally, the address in the program counter automatically increments to the next sequential memory location every time an instruction or operand is fetched. Jump, branch, and interrupt operations load the program counter with an address other than that of the next sequential location.

Figure 3-5. Program Counter (PC)

### 3.1.5 Condition Code Register (CCR)

The condition code register shown in Figure 3-6 is an 8-bit register whose three most significant bits are permanently fixed at 111. The condition code register contains the interrupt mask and four flags that indicate the results of the instruction just executed. The following paragraphs describe the functions of the condition code register.

Figure 3-6. Condition Code Register (CCR)

#### 3.1.5.1 Half-Carry Flag (H)

The CPU sets the half-carry flag (H) when a carry occurs between bits 3 and 4 of the accumulator during an ADD or ADC operation. The half-carry flag is required for binary-coded decimal (BCD) arithmetic operations.

### 3.1.5.2 Interrupt Mask (I)

Setting the interrupt mask (I) disables interrupts. If an interrupt request occurs while the interrupt mask is zero, the CPU saves the CPU registers on the stack, sets the interrupt mask, and then fetches the interrupt vector. If an interrupt request occurs while the interrupt mask is set, the interrupt request is latched. Normally, the CPU processes the latched interrupt as soon as the interrupt mask is cleared again.

A return from interrupt (RTI) instruction pulls the CPU registers from the stack, restoring the interrupt mask to its cleared state. After any reset, the interrupt mask is set and can be cleared only by a software instruction.

### 3.1.5.3 Negative Flag (N)

The CPU sets the negative flag (N) when an arithmetic operation, logical operation, or data manipulation produces a negative result. Bit 7 of the negative result is automatically set, so the negative flag can be used to check an often-tested bit by assigning it to bit 7 of a register or memory location. Loading the accumulator with the contents of that register or location then sets or clears the negative flag according to the state of the tested bit.

### 3.1.5.4 Zero Flag (Z)

The CPU sets the zero flag (Z) when an arithmetic operation, logical operation, or data manipulation produces a \$00.

### 3.1.5.5 Carry/Borrow Flag (C)

The CPU sets the carry/borrow flag (C) when an addition operation produces a carry out of bit 7 of the accumulator. Bit test and branch instructions and shifts and rotates also clear or set the carry/borrow flag.

### 3.2 Arithmetic/Logic Unit (ALU)

The ALU performs the arithmetic and logical operations defined by the instruction set.

The binary arithmetic circuits decode instructions and set up the ALU for the selected operation. Most binary arithmetic is based on the addition algorithm, carrying out subtraction as negative addition. Multiplication is not performed as a discrete operation but as a chain of addition and shift operations within the ALU. The multiply instruction (MUL) requires 11 internal processor cycles to complete this chain of operations.

## SECTION 4 INTERRUPTS

This section describes how interrupts temporarily change the normal processing sequence.

### 4.1 Interrupt Types

The following sources can generate interrupts:

- SWI instruction
- $\overline{\text{IRQ}}$  pin
- Capture/Compare timer
- Serial peripheral interface (SPI)
- Serial communications interface (SCI)

An interrupt temporarily stops normal program execution to process a particular event. An interrupt does not stop the operation of the instruction being executed, but takes effect when the current instruction completes its execution.

When the current instruction is complete, the processor checks all pending hardware interrupts. If interrupts are not masked (condition code register I bit clear) and if the corresponding interrupt enable bit is set, the processor proceeds with interrupt processing; otherwise, the next instruction is fetched and executed.

Interrupt processing automatically saves the CPU registers on the stack and loads the program counter with a user-defined interrupt vector address. (Table 4-1 lists vector addresses for all interrupts including reset.)

#### 4.1.1 Software Interrupt

The software interrupt (SWI) instruction causes a nonmaskable interrupt.

### 4.1.2 External Interrupt

An interrupt signal on the  $\overline{\text{IRQ}}$  pin latches an external interrupt request. When the CPU completes its current instruction, it tests the IRQ latch. If the IRQ latch is set, the CPU then tests the I bit in the condition code register. If the I bit is clear, the CPU then begins the interrupt sequence.

The CPU clears the  $\overline{\text{IRQ}}$  latch during interrupt processing, so that another interrupt signal on the  $\overline{\text{IRQ}}$  pin can latch another interrupt request during the interrupt service routine. As soon as the I bit is cleared during the return from interrupt, the CPU can recognize the new interrupt request. Figure 4-1 shows the  $\overline{\text{IRQ}}$  pin interrupt logic.

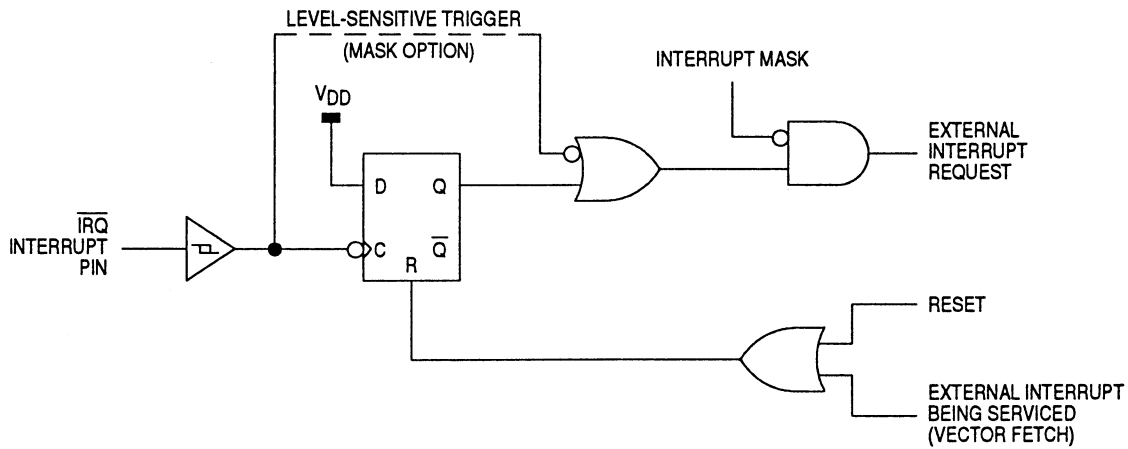

Figure 4-1. External Interrupt Trigger Option

Setting the I bit in the condition code register disables external interrupts.

The  $\overline{\text{IRQ}}$  pin can be edge-sensitive, or edge- and level-sensitive, depending on the mask option. (See **1.2 Mask Options**.) The level-sensitive trigger option allows multiple external interrupt sources to be wire-ORed to the  $\overline{\text{IRQ}}$  pin. As long as any source is holding the  $\overline{\text{IRQ}}$  pin low, an external interrupt request is latched.

### 4.1.3 Capture/Compare Timer Interrupts

The capture/compare timer can generate the following interrupts:

- Input capture interrupt
- Output compare interrupt
- Timer overflow interrupt

Setting the I bit in the condition code register disables timer interrupts.

#### 4.1.3.1 Input Capture Interrupt

An input capture interrupt request occurs if the input capture flag (ICF) becomes set while the input capture interrupt enable bit (ICIE) is also set. ICF is in the timer status register and ICIE is in the timer control register. (See **SECTION 8 CAPTURE/COMPARE TIMER.**)

#### 4.1.3.2 Output Compare Interrupt

An output compare interrupt request occurs if the output compare flag (OCF) becomes set while the output compare interrupt enable bit (OCIE) is also set. OCF is in the timer status register and OCIE is in the timer control register. (See **SECTION 8 CAPTURE/COMPARE TIMER.**)

#### 4.1.3.3 Timer Overflow Interrupt

A timer overflow interrupt request occurs if the timer overflow flag (TOF) becomes set while the timer overflow interrupt enable bit (TOIE) is also set. TOF is in the timer status register, and TOIE is in the timer control register. (See **SECTION 8 CAPTURE/COMPARE TIMER.**)

### 4.1.4 SCI Interrupt

An SCI interrupt occurs when one of the interrupt flag bits in the SCI status register (SCSR) is set while the SCI transmit interrupt enable bit (TIE) in the serial communications control register 2 (SCCR2) is also set. Software in the SCI interrupt service routine must determine the interrupt flag bits in SCSR to determine the cause and priority of the SCI interrupt. (See **SECTION 9 SERIAL COMMUNICATIONS INTERFACE.**)

### 4.1.5 SPI Interrupt

An SPI interrupt occurs when one of the interrupt flag bits in the SPI status register (SPSR) is set while the serial peripheral interrupt enable bit (SPIE) in the serial peripheral control register (SPCR) is also set. Software in the SPI interrupt service routine must determine the interrupt flag bits in SPSR to determine the cause and priority of the SPI interrupt. (See **SECTION 10 SERIAL PERIPHERAL INTERFACE.**)

Table 4-1 shows reset and interrupt vector assignments.

**Table 4-1. Reset/Interrupt Vector Assignments**

Type	Source	Local Mask	Global Mask	Priority (1 = High)	Vector Address
Reset	Reset Pin POR	None None	None None	1 1	\$3FFE–\$3FFF \$3FFE–\$3FFF
Software Interrupt (SWI)	User Code	None	None	Same Priority As Instruction	\$3FFC–\$3FFD
External	$\overline{\text{IRQ}}$ Pin	None	1 Bit	2	\$3FFA–\$3FFB
Timer Vector	ICF OCF TOF	ICIE OCIE TOIE	1 Bit	3	\$3FF8–\$3FF9
SCI Vector	TDRE	TIE	1 Bit	4	\$3FF6–\$3FF7
SPI Vector	SPIF	SPIE	1 Bit	5	\$3FF4–\$3FF5

Figure 4-3 shows the sequence of events caused by an interrupt.

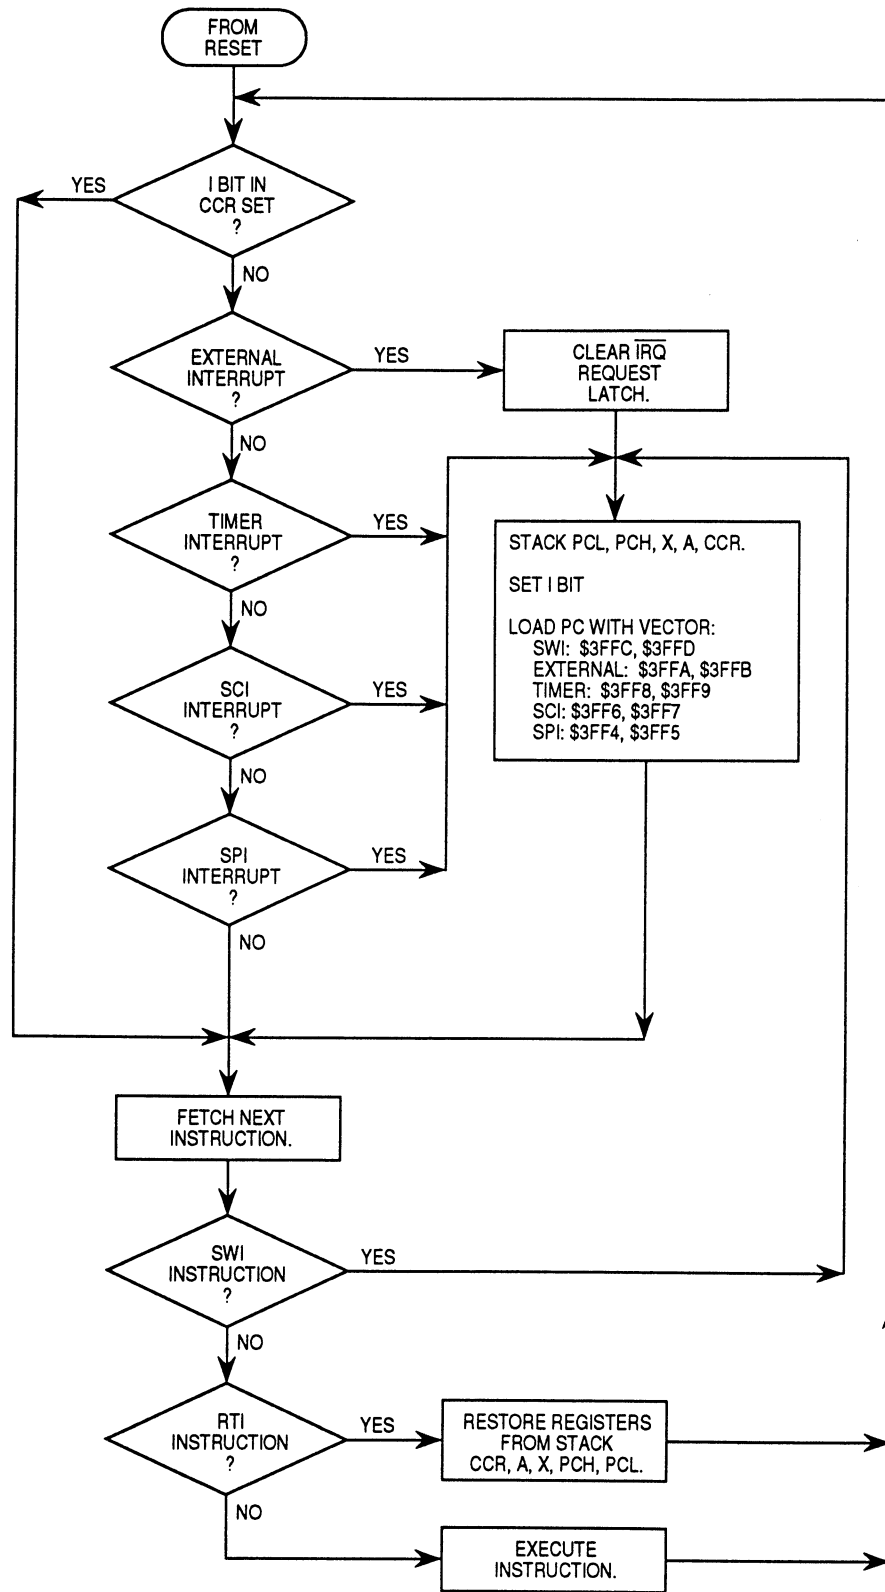

Figure 4-3. Reset and Interrupt Processing Flowchart

## SECTION 5 RESETS

This section describes how resets initialize the MCU.

### 5.1 Reset Sources

The following sources can generate resets:

- Power-on reset (POR) circuit
- $\overline{\text{RESET}}$  pin
- COP watchdog

A reset immediately stops the operation of the instruction being executed, initializes certain control bits, and loads the program counter with a user-defined reset vector address. Figure 5-1 is a block diagram of the reset sources.

#### 5.1.1 Power-On Reset

A positive transition on the  $V_{DD}$  pin generates a power-on reset. The power-on reset is strictly for power-up conditions and cannot be used to detect drops in power supply voltage.

#### 5.1.2 External Reset

A logic zero applied to the  $\overline{\text{RESET}}$  pin for  $1\frac{1}{2} t_{CYC}$  generates an external reset. A Schmitt trigger senses the logic level at the  $\overline{\text{RESET}}$  pin. (See Figure 5-1.)

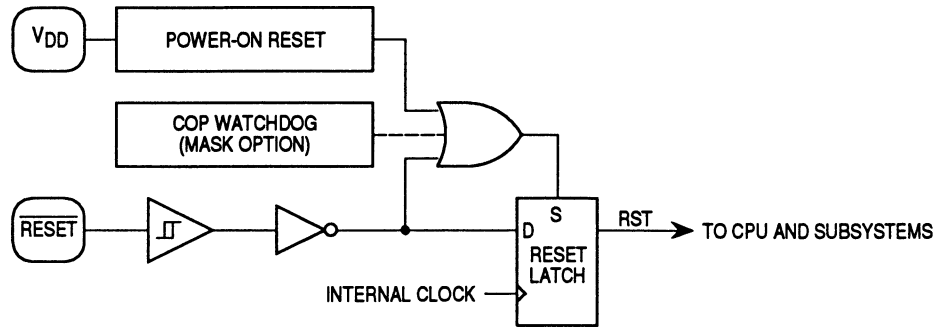

Figure 5-1. Reset Sources

### 5.1.3 Computer Operating Properly (COP) Watchdog Reset

A timeout of the COP watchdog generates a COP reset, and the device will be re-initialized in the same fashion as a POR or external reset. The mask optional COP watchdog is part of a software error detection system and must be cleared periodically to start a new timeout period. The COP is implemented with an 18-bit ripple counter, providing a timeout period of 64 ms at a bus rate of 2 MHz.

To clear the COP watchdog and prevent a COP reset, write a logic zero to bit 0 (COPC) of the COP register at location \$3FF0. The COP register, shown in Figure 5-2, is a write-only register. A read of COPR returns the contents of reserved ROM data at that location.

The COP watchdog function is a mask option.

**COPR — COP Register**

**\$3FF0**

Figure 5-2. COP Register (COPR)

**COPC — COP Clear**

COPC is a write-only bit. Periodically writing a logic zero to COPC prevents the COP watchdog from resetting the MCU. A reset clears the COPC bit.

## 5.2 Reset States

The following paragraphs describe how resets initialize the MCU.

### 5.2.1 CPU

A reset has the following effects on the CPU:

- Loads the stack pointer with \$FF
- Sets the I bit in the condition code register, inhibiting interrupts
- Loads the program counter with the user-defined reset vector from locations \$3FFE and \$3FFF
- Clears the stop latch, enabling the CPU clock
- Clears the wait latch, waking the CPU from the wait mode

### 5.2.2 I/O Port Registers

A reset has the following effects on I/O port registers:

- Clears ports A, B, and C data direction registers so that all corresponding I/O port pins are inputs
- Has no effect on port data registers

### 5.2.3 Capture/Compare Timer

A reset has the following effects on the capture/compare timer:

- Loads the timer counter with \$FFFC
- Clears the timer control register, except for the IEDG bit, with the following results:
  - Clears the ICIE bit, inhibiting input capture interrupts
  - Clears the OCIE bit, inhibiting output compare interrupts
  - Clears the TOIE bit, inhibiting timer overflow interrupts
  - Clears OLVL, the output compare bit
  - Clears the TCMP pin
- Has no effect on the ICF, OCF, and TOF flags in the timer status register

#### 5.2.4 SCI

A reset has the following effects on the SCI registers:

- Clears control bits (RDRF, IDLE, OR, NF, FE); sets TDRE and TC to 1
- Clears serial communications control register 2
- Does not affect bits in serial communications control register 1
- Does not affect bits in serial communications data register

#### 5.2.5 SPI

A reset has the following effects on the SPI registers:

- Clears flags in SPI status register (SPIF, WCOL, MODF)
- Clears control bits in SPI control register (SPIE, SPE, MSTR); bits pertaining to clock unaffected (CPOL, CPHA, SPR1:0)
- Does not affect bits in SPI data register

#### 5.2.6 COP Watchdog

A reset clears the COP watchdog counter.

## SECTION 6 LOW POWER MODES

This section describes the two low power modes:

- Stop
- Wait

This section also describes the timer, SCI, SPI and the COP in stop and wait modes.

### 6.1 Stop Mode

The STOP instruction puts the MCU in its lowest power-consumption mode and has the following effects on the MCU:

- Stops the internal oscillator, halting all internal processing including timer, SCI, and SPI in master mode operations
- Clears I bit in condition code register, enabling external interrupts

The STOP instruction does not affect any other register or I/O lines.

The MCU can be brought out of the stop mode only by the following conditions:

- An external interrupt signal on the  $\overline{\text{IRQ}}$  pin — A high-to-low transition on the  $\overline{\text{IRQ}}$  pin loads the program counter with the contents of locations \$3FFA and \$3FFB. The timer resumes counting from the last value before the STOP instruction.
- External reset — A logic zero on the  $\overline{\text{RESET}}$  pin resets the MCU and loads the program counter with the contents of locations \$3FFE and \$3FFF. The timer begins counting from \$FFFC.

Figure 6-1 shows the sequence of events caused by the STOP instruction.

Figure 6-1. STOP Instruction Flowchart

### 6.1.1 Timer during Stop Mode

The capture/compare timer stops counting in stop mode and holds the last count value. If  $\overline{\text{IRQ}}$  is used to exit stop mode, the timer resumes counting from the count value present when stop mode was entered. If  $\overline{\text{RESET}}$  is used to exit stop mode, the counter is forced to \$FFFC.

An active edge on the TCAP pin during stop mode sets the ICF flag when an external interrupt brings the MCU out of stop mode. An external interrupt also latches the value in the timer registers (TRH and TRL) into the input capture registers (ICRH and ICRL).

If a power-on reset or a logic zero on the  $\overline{\text{RESET}}$  pin brings the MCU out of stop mode, all timer interrupt enable bits are cleared.

### 6.1.2 SCI during Stop Mode

When the MCU enters stop mode, the baud rate generator stops, halting all SCI activity. If the STOP instruction is executed during a transmitter transfer, that transfer is halted. If a low input to the  $\overline{\text{IRQ}}$  pin is used to exit stop mode, the transfer resumes.

If the SCI receiver is receiving data and the stop mode is entered, received data sampling stops because the baud rate generator stops, and all subsequent data is lost. For these reasons, all SCI transfers should be in the idle state when the STOP instruction is executed.

### 6.1.3 SPI during Stop Mode

When the MCU enters stop mode, the baud rate generator stops, terminating all master mode SPI operations. If the STOP instruction is executed during an SPI transfer, that transfer halts until the MCU exits the stop mode by a low signal on the  $\overline{\text{IRQ}}$  pin.

If reset is used to exit stop mode, then the SPI control and status bits are cleared and the SPI is disabled.

If the MCU is in slave mode when the STOP instruction is executed, the slave SPI continues to operate and can still accept data and clock information in addition to transmitting its own data back to a master device.

At the end of a possible transmission with a slave SPI in the stop mode, no flags are set until a low on the  $\overline{\text{IRQ}}$  pin wakes up the MCU. Care should be taken when operating the SPI as a slave during the stop mode because the protective circuitry (WCOL, MODF) is inactive.

### 6.1.4 COP during Stop Mode

Entering stop mode halts COP timer operations (mask optional) and causes a reset of the COP counter. If a reset is used to exit stop mode, the COP counter will be reset after the 4064 cycles of delay after stop mode. If an IRQ is used to exit stop mode, the COP counter will not be reset after the 4064 cycle delay, but will have that number of cycles already counted when control is returned to the program.

## 6.2 Wait Mode

The WAIT instruction puts the MCU in an intermediate power-consumption mode. All CPU activity is suspended, but the oscillator, capture/compare timer, SCI, and SPI remain active. Any interrupt or reset will cause the MCU to exit wait mode.

The mask optional COP will continue to operate normally during wait mode. To prevent a COP reset, the software should pull the device out of wait mode periodically and write a logic zero to COPC in the COP register (COPR).

The WAIT instruction has the following effects on the MCU:

- Clears the I bit in the condition code register, enabling interrupts
- Stops the CPU clock, but allows the internal clock to drive the capture/compare timer, SCI, and SPI

The WAIT instruction does not affect any other registers, I/O lines, or memory. The capture/compare timer, SCI, and SPI can be enabled to allow a periodic exit from the wait mode.

The following conditions bring the MCU out of wait mode:

- External interrupt — A high-to-low transition on the  $\overline{\text{IRQ}}$  pin loads the program counter with the contents of locations \$3FFA and \$3FFB (IRQ vector).
- Timer interrupt — Input capture, output compare, and timer overflow interrupt requests load the program counter with the contents of locations \$3FF8 and \$3FF9 (timer vector).
- SCI interrupt — An SCI interrupt loads the program counter with the contents of locations \$3FF6 and \$3FF7 (SCI vector).
- SPI interrupt — An SPI interrupt loads the program counter with the contents of locations \$3FF4 and \$3FF5 (SPI vector).

- COP watchdog reset — A timeout of the COP watchdog resets the MCU and loads the program counter with the contents of locations \$3FFE and \$3FFF (reset vector). Software can enable timer interrupts so that the MCU can periodically exit wait mode to reset the COP watchdog.
- External reset — A logic zero on the  $\overline{\text{RESET}}$  pin resets the MCU and loads the program counter with the contents of locations \$3FFE and \$3FFF (reset vector).

Figure 6-2 shows the sequence of events caused by the WAIT instruction.

**Figure 6-2. WAIT Instruction Flowchart**

The following figure shows the effect of the STOP and WAIT instructions on the CPU clock and the internal clock.

**Figure 6-3. STOP/WAIT Clock Logic**

## SECTION 7 PARALLEL I/O

This section describes the three bidirectional I/O ports A, B, and C, and one 7-bit input-only port D that shares its pins with the SCI and SPI.

### 7.1 I/O Port Function

Each of the 24 I/O pins is programmable as an input or an output under software control of the data direction registers (DDRs). Writing a one to a data direction register bit enables the output buffer for the associated port pin; a zero disables the output buffer. Reset configures all I/O pins as inputs. A reset does not initialize the three port data registers.

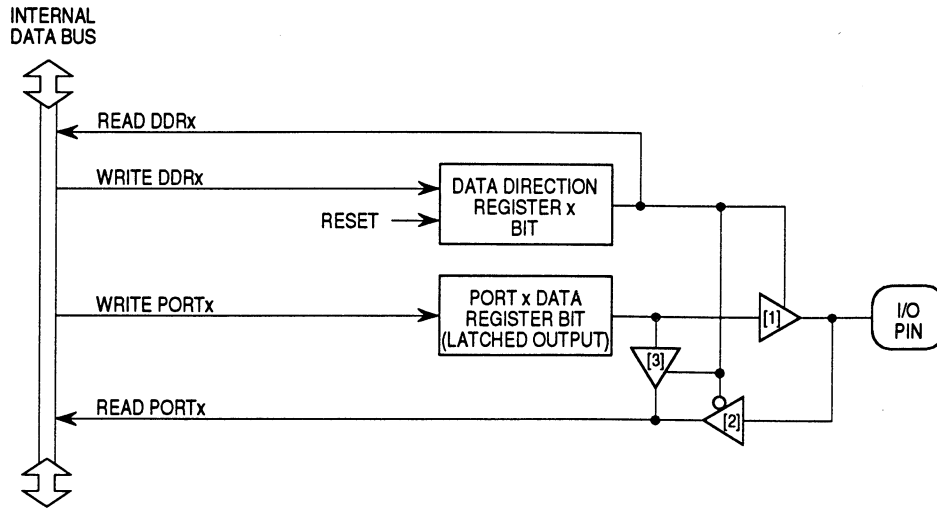

#### NOTE

To avoid a glitch on the output pins, write data to the I/O port data register before writing a one to the corresponding data direction register.

With an I/O port pin programmed as an output, reading the pin actually reads the value of the output data latch and not the voltage on the pin itself. When a pin is programmed as an input, reading the port bit reads the voltage level on the I/O pin. The output data latch can always be written, regardless of the state of its DDR bit. Refer to Figure 7-1 for typical port circuitry and to Table 7-1 for a summary of I/O pin functions.

#### NOTE

Connect any unused inputs and I/O pins to an appropriate logic level, either  $V_{DD}$  or  $V_{SS}$ . Although the I/O ports do not require termination for proper operation, termination reduces excess current consumption and the possibility of electrostatic damage.

- [1] This output buffer enables the latched output to drive the pin when DDR bit is 1 (output mode).
- [2] This input buffer is enabled when DDR bit is 0 (input mode).
- [3] This input buffer is enabled when DDR bit is 1 (output mode).

Figure 7-1. Parallel Port I/O Circuitry

Table 7-1. I/O Pin Functions

R/W	DDR	I/O Pin Functions
0	0	The I/O pin is in input mode. Data is written into the output data latch.
0	1	Data is written into the output data latch, which drives the I/O pin.
1	0	The state of the I/O pin is read.
1	1	The I/O pin is in output mode. The output data latch is read.

NOTE: R/W is an internal signal.

## 7.2 Port A

Port A is an 8-bit general-purpose bidirectional I/O port.

### 7.2.1 Port A Data Register (PORTA)

The port A data register, shown in Figure 7-2, contains a data latch for each of the eight port A pins. Reset does not affect the data registers.

**PORTA** — Port A Data Register **\$0000**

**Figure 7-2. Port A Data Register**

**PA7–PA0** — Port A Data Bits

These read/write bits are software-programmable. Data direction of each bit is under control of the corresponding bit in data direction register A.

### 7.2.2 Data Direction Register A (DDRA)

Data direction register A, shown in Figure 7-3, determines whether each port A pin is an input or an output. Writing a logic one to a DDRA bit enables the output buffer for the corresponding port A pin; a logic zero disables the output buffer. A reset clears all DDRA bits, configuring all port A pins as inputs.

**DDRA** — Data Direction Register A **\$0004**

**Figure 7-3. Data Direction Register A (DDRA)**

**DDRA7–DDRA0** — Port A Data Direction Bits

- These read/write bits control port A data direction.
- 1 = Corresponding port A pin configured as output
- 0 = Corresponding port A pin configured as input

### 7.3 Port B

Port B is an 8-bit general-purpose bidirectional I/O port.

#### 7.3.1 Port B Data Register (PORTB)

The port B data register, shown in Figure 7-4, contains a data latch for each of the eight port B pins. Reset does not affect the data registers.

**PORTB** — Port B Data Register **\$0001**

**Figure 7-4. Port B Data Register**

PB7–PB0 — Port B Data Bits

These read/write bits are software-programmable. Data direction of each bit is under control of the corresponding DDRB bit.

#### 7.3.2 Data Direction Register B (DDRB)

Data direction register B, shown in Figure 7-5, determines whether each port B pin is an input or an output. Writing a logic one to a DDRB bit enables the output buffer for the corresponding port B pin; a logic zero disables the output buffer. A reset clears all DDRB bits, configuring all port B pins as inputs.

**DDRB** — Data Direction Register B **\$0005**

**Figure 7-5. Data Direction Register B**

DDRB7–DDRB0 — Port B Data Direction Bits

These read/write bits control port B data direction.

1 = Corresponding port B pin configured as output

0 = Corresponding port B pin configured as input

### 7.3.3 Port B Mask Optional Interrupts

Each of the port B pins has an optional pullup device that can be enabled with a mask option. When the pullup device is enabled, this pin can become an interrupt pin. The edge- or edge- and level-sensitivity of the  $\overline{IRQ}$  pin will pertain to the enabled port B pin(s). Figure 7-6 illustrates the port B pullup option.

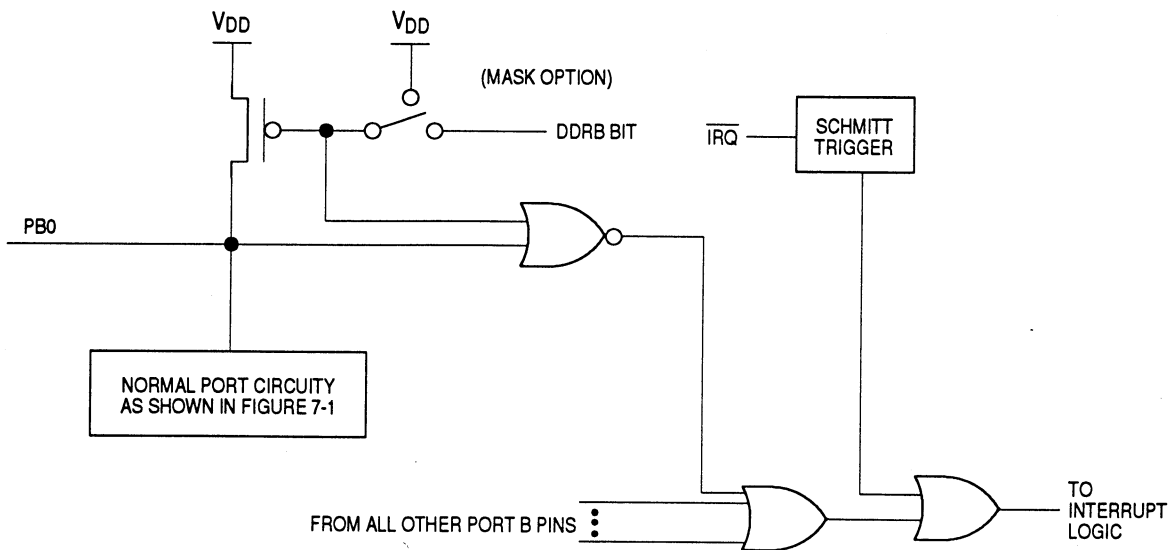

Figure 7-6. Port B Pullup Option

#### NOTE

Be careful when using port B pins with pullups enabled. Before switching from an output to an input, precondition the data to a 1 to prevent an interrupt.

## 7.4 Port C

Port C is an 8-bit general-purpose bidirectional I/O port.

### 7.4.1 Port C Data Register (PORTC)

The port C data register, shown in Figure 7-7, contains a data latch for each of the eight port C pins. Reset does not affect the data registers.

PC7 has a high current sink and source capability.

**PORTC — Port C Data Register** **\$0002**

**Figure 7-7. Port C Data Register**

#### PC7–PC0 — Port C Data Bits

These read/write bits are software-programmable. Data direction of each bit is under control of the corresponding DDRC bit.

### 7.4.2 Data Direction Register C (DDRC)

Data direction register C, shown in Figure 7-8, determines whether each port C pin is an input or an output. Writing a logic one to a DDRC bit enables the output buffer for the corresponding port C pin; a logic zero disables the output buffer. A reset clears all DDRC bits, configuring all port C pins as inputs.

**DDRC — Data Direction Register C** **\$0006**

**Figure 7-8. Data Direction Register C**

#### DDRC7–DDRC0 — Port C Data Direction Bits

- These read/write bits control port C data direction.
- 1 = Corresponding port C pin configured as output
  - 0 = Corresponding port C pin configured as input

## 7.5 Port D

Port D is a 7-bit fixed-input port. Four of its pins are shared with the SPI subsystem and two more are shared with the SCI subsystem.

### 7.5.1 Port D Register (PORTD)

No data register is associated with port D when it is used as an input. During reset, all 7 bits become valid input ports because all special-function output drivers associated with the SCI and SPI subsystems are disabled. Figure 7-9 shows port D register and port D alternate pin functions.

**PORTD — Port D Register** **\$0003**

	Bit 7	6	5	4	3	2	1	Bit 0
	PD7	—	PD5	PD4	PD3	PD2	PD1	PD0
RESET:	NOT CHANGED BY RESET							
ALTERNATE FUNCTION:	—	—	$\overline{SS}$	SCK	MOSI	MISO	TDO	RDI

**Figure 7-9. Port D Register**

## SECTION 8 CAPTURE/COMPARE TIMER

This section describes the operation of the 16-bit capture/compare timer. Figure 8-1 shows the organization of the capture/compare timer subsystem.

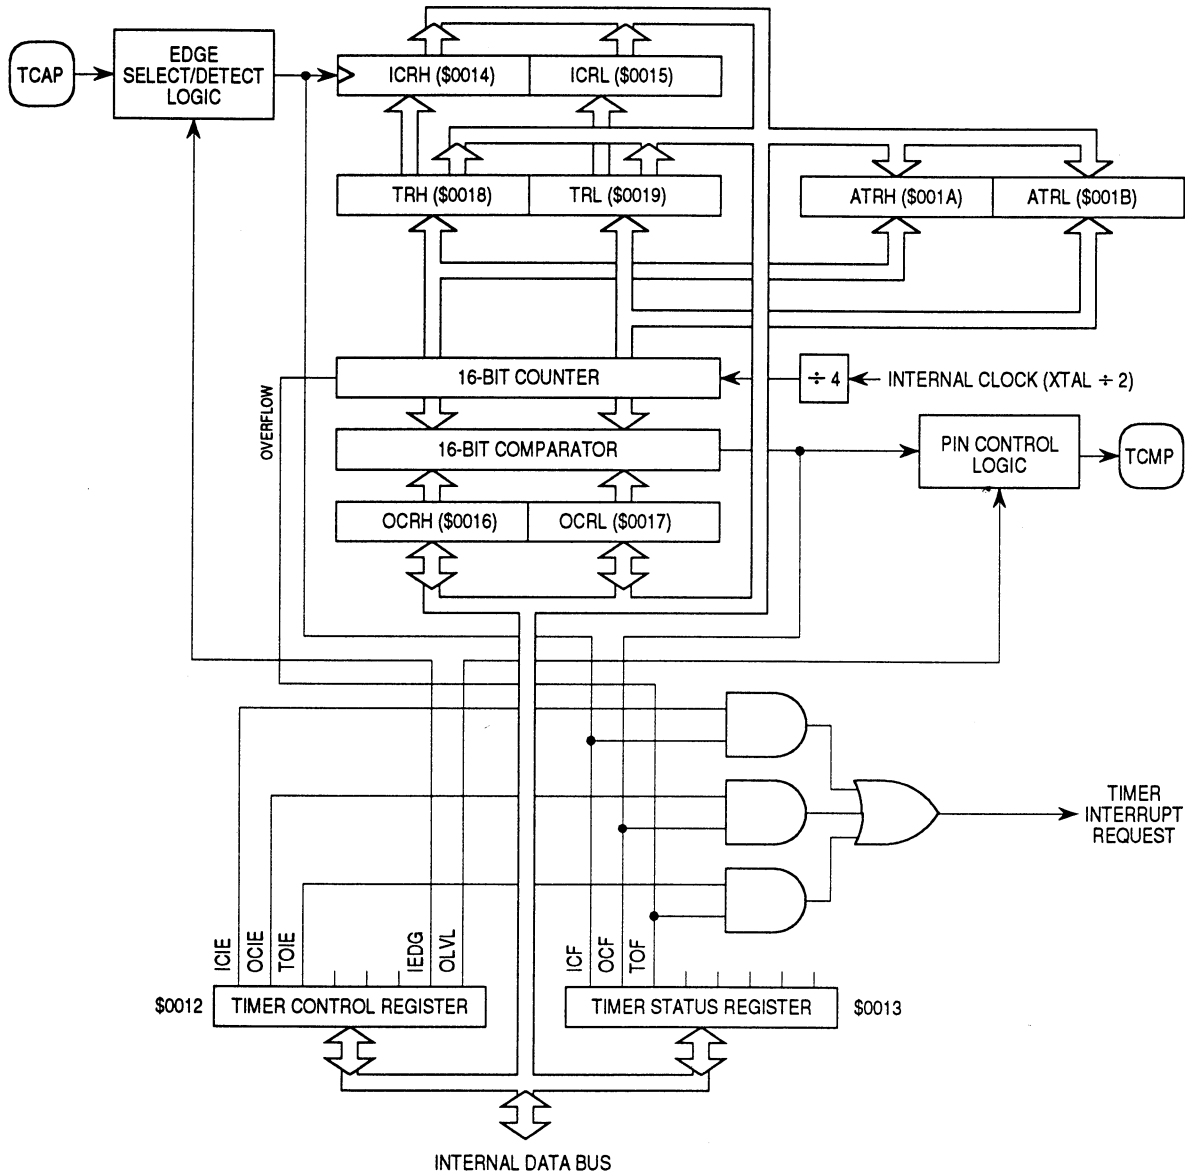

Figure 8-1. Capture/Compare Timer Block Diagram

## 8.1 Timer Operation

The core of the capture/compare timer is a 16-bit free-running counter. The counter provides the timing reference for the input capture and output compare functions. The input capture and output compare functions provide a means to latch the times at which external events occur, to measure input waveforms, and to generate output waveforms and timing delays. Software can read the value in the 16-bit free-running counter at any time without affecting the counter sequence.

Because of the 16-bit timer architecture, the I/O registers for the input capture and output compare functions are pairs of 8-bit registers.

Because the counter is 16 bits long and preceded by a fixed divide-by-four prescaler, the counter rolls over every 262,144 internal clock cycles. Timer resolution with a 4-MHz crystal is 2  $\mu$ s.

### 8.1.1 Input Capture

The input capture function is a means to record the time at which an external event occurs. When the input capture circuitry detects an active edge on the TCAP pin, it latches the contents of the timer registers into the input capture registers. The polarity of the active edge is programmable.

Latching values into the input capture registers at successive edges of the same polarity measures the period of the input signal on the TCAP pin. Latching the counter values at successive edges of opposite polarity measures the pulse width of the signal. Figure 8-2 shows the logic of the input capture function.

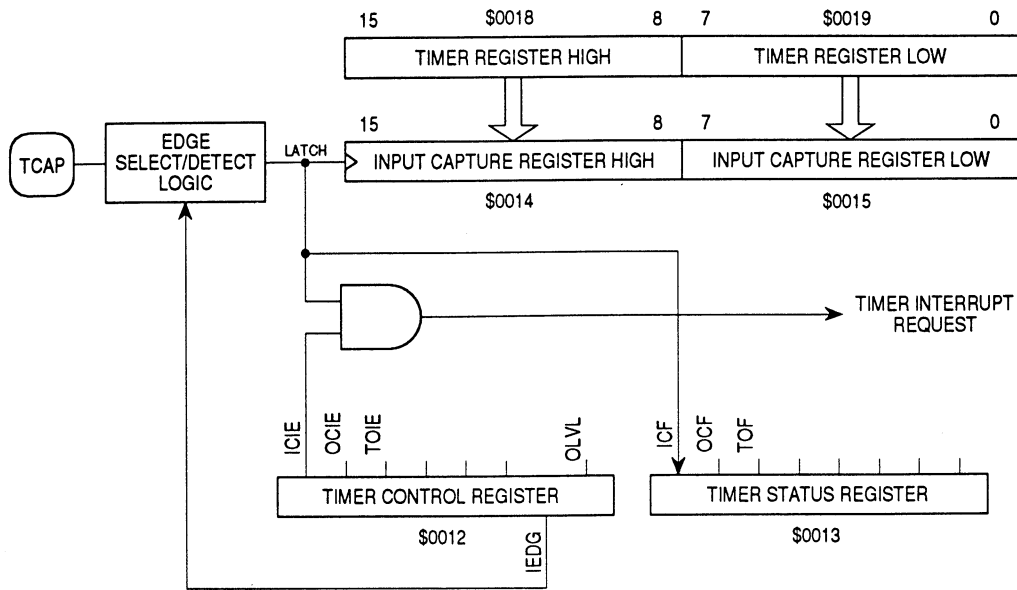

Figure 8-2. Input Capture Operation

### 8.1.2 Output Compare

The output compare function is a means of generating an output signal when the 16-bit counter reaches a selected value. Software writes the selected value into the output compare registers. On every fourth internal clock cycle the output compare circuitry compares the value of the counter to the value written in the output compare registers. When a match occurs, the timer transfers the programmable output level bit (OLVL) from the timer control register to the TCMP pin.

The programmer can use the output compare register to measure time periods, to generate timing delays, or to generate a pulse of specific duration or a pulse train of specific frequency and duty cycle on the TCMP pin. Figure 8-3 shows the logic of the output compare function.

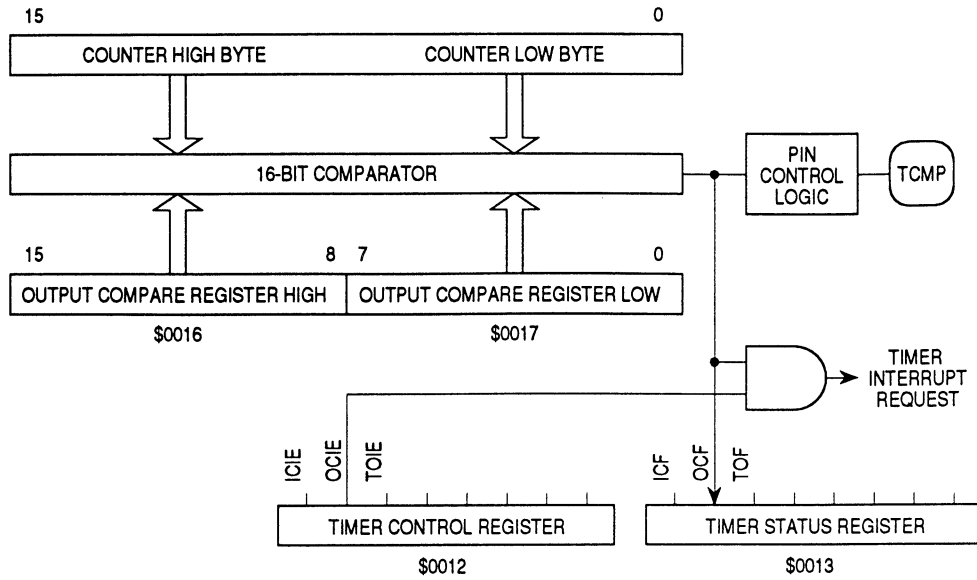

Figure 8-3. Output Compare Operation

## 8.2 Timer I/O Registers

The following registers control and monitor the operation of the timer:

- Timer control register (TCR)
- Timer status register (TSR)
- Timer registers (TRH and TRL)
- Alternate timer registers (ATRH and ATRL)
- Input capture registers (ICRH and ICRL)
- Output compare registers (OCRH and OCRL)

### 8.2.1 Timer Control Register (TCR)

The timer control register, shown in Figure 8-4, performs the following functions:

- Enables input capture interrupts
- Enables output compare interrupts
- Enables timer overflow interrupts
- Controls the active edge polarity of the TCAP signal
- Controls the active level of the TCMP output

**TCR** — Timer Control Register

**\$0012**

	Bit 7	6	5	4	3	2	1	Bit 0
	ICIE	OCIE	TOIE	0	0	0	IEDG	OLVL
RESET:	0	0	0	0	0	0	U	0

U = UNAFFECTED

**Figure 8-4. Timer Control Register (TCR)**

**ICIE** — Input Capture Interrupt Enable

This read/write bit enables interrupts caused by an active signal on the TCAP pin. Resets clear the ICIE bit.

- 1 = Input capture interrupts enabled
- 0 = Input capture interrupts disabled

**OCIE** — Output Compare Interrupt Enable

This read/write bit enables interrupts caused by an active signal on the TCMP pin. Resets clear the OCIE bit.

- 1 = Output compare interrupts enabled
- 0 = Output compare interrupts disabled

**TOIE** — Timer Overflow Interrupt Enable

This read/write bit enables interrupts caused by a timer overflow. Resets clear the TOIE bit.

- 1 = Timer overflow interrupts enabled
- 0 = Timer overflow interrupts disabled

**IEDG — Input Edge**

The state of this read/write bit determines whether a positive or negative transition on the TCAP pin triggers a transfer of the contents of the timer register to the input capture register. Resets have no effect on the IEDG bit.

- 1 = Positive edge (low to high transition) triggers input capture
- 0 = Negative edge (high to low transition) triggers input capture

**OLVL — Output Level**

The state of this read/write bit determines whether a logic one or a logic zero appears on the TCMP pin when a successful output compare occurs. Resets clear the OLVL bit.

- 1 = TCMP goes high on output compare
- 0 = TCMP goes low on output compare

**8.2.2 Timer Status Register (TSR)**

The timer status register, shown in Figure 8-5, contains flags for the following events:

- An active signal on the TCAP pin, transferring the contents of the timer registers to the input capture registers
- A match between the 16-bit counter and the output compare registers, transferring the OLVL bit to the TCMP pin
- A timer rollover from \$FFFF to \$0000

**TSR — Timer Status Register**

**\$0012**

	Bit 7	6	5	4	3	2	1	Bit 0
	ICF	OCF	TOF	0	0	0	0	0
RESET:	U	U	U	0	0	0	0	0

U = UNAFFECTED

**Figure 8-5. Timer Status Register (TSR)**

**ICF — Input Capture Flag**

The ICF bit is automatically set when an edge of the selected polarity occurs on the TCAP pin. Clear the ICF bit by reading the timer status register with ICF set, and then reading the low byte (\$0015) of the input capture registers. Resets have no effect on ICF.

**OCF — Output Compare Flag**

The OCF bit is automatically set when the value of the timer registers matches the contents of the output compare registers. Clear the OCF bit by reading the timer status register with OCF set, and then accessing the low byte (\$0017) of the output compare registers. Resets have no effect on OCF.

**TOF — Timer Overflow Flag**

The TOF bit is automatically set when the 16-bit counter rolls over from \$FFFF to \$0000. Clear the TOF bit by reading the timer status register with TOF set, and then accessing the low byte (\$0019) of the timer registers. Resets have no effect on TOF.

**8.2.3 Timer Registers (TRH and TRL)**

The timer registers, shown in Figure 8-6, contain the current high and low bytes of the 16-bit counter. Reading TRH before reading TRL causes TRL to be latched until TRL is read. Reading TRL after reading the timer status register clears the timer overflow flag (TOF). Writing to the timer registers has no effect.

**TRH and TRL — Timer Registers High/Low \$0018 and \$0019**

\$0018	Bit 15	14	13	12	11	10	9	Bit 8
\$0019	Bit 7	6	5	4	3	2	1	Bit 0

Reset initializes the timer registers to \$FFFC.

**Figure 8-6. Timer Registers (TRH and TRL)**

Reading TRH returns the current value of the high byte of the counter and causes the low byte to be latched into a buffer, as shown in Figure 8-7. The buffer value remains fixed even if the high byte is read more than once. Reading TRL reads the transparent low byte buffer and completes the read sequence of the timer registers.

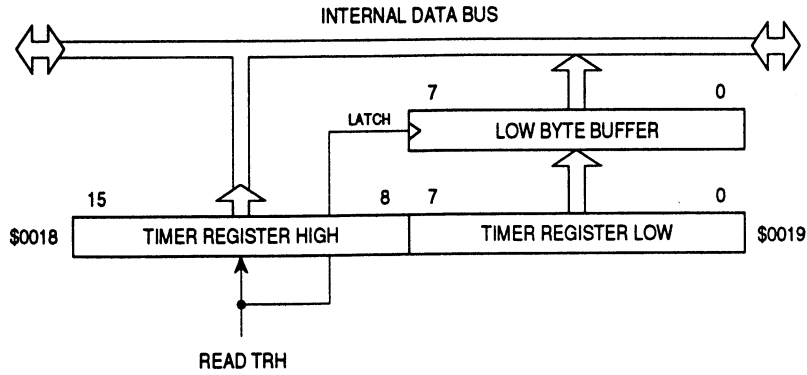

Figure 8-7. Timer Register Reads

**NOTE**

To prevent interrupts from occurring between readings of TRH and TRL, set the interrupt flag in the condition code register before reading TRH, and clear the flag after reading TRL.

**8.2.4 Alternate Timer Registers (ATRH and ATRL)**

The alternate timer registers, shown in Figure 8-8, contain the current high and low bytes of the 16-bit counter. Reading ATRH before reading ATRL causes ATRL to be latched until ATRL is read. Reading does not affect the timer overflow flag (TOF). Writing to the alternate timer registers has no effect.

**ATRH and ATRL — Alternate Timer Registers High/Low \$001A and \$001B**

\$001A	Bit 15	14	13	12	11	10	9	Bit 8
\$001B	Bit 7	6	5	4	3	2	1	Bit 0

Reset initializes the alternate timer registers to \$FFFC.

Figure 8-8. Alternate Timer Registers (ATRH and ATRL)

Reading ATRH returns the current value of the high byte of the counter and causes the low byte to be latched into a buffer, as shown in Figure 8-9. The buffer value remains fixed even if the high byte is read more than once. Reading ATRL reads the transparent low byte buffer and completes the read sequence of the alternate timer registers.

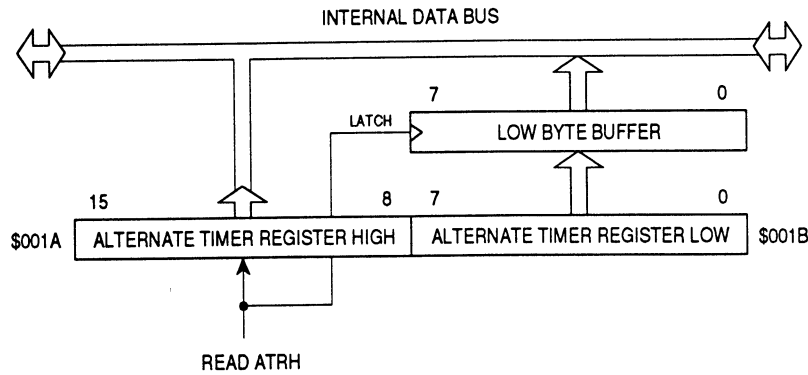

Figure 8-9. Alternate Timer Register Reads

**NOTE**

To prevent interrupts from occurring between readings of ATRH and ATRL, set the interrupt flag in the condition code register before reading ATRH, and clear the flag after reading ATRL.

**8.2.5 Input Capture Registers (ICRH and ICRL)**

When a selected edge occurs on the TCAP pin, the current high and low bytes of the 16-bit counter are latched into the input capture registers. Reading ICRH before reading ICRL inhibits further captures until ICRL is read. Reading ICRL after reading the timer status register clears the input capture flag (ICF). Writing to the input capture registers has no effect.

**ICRH and ICRL — Input Capture Registers High/Low \$0014 and \$0015**

\$0014	Bit 15	14	13	12	11	10	9	Bit 8
\$0015	Bit 7	6	5	4	3	2	1	Bit 0

Reset does not affect the input capture registers.

Figure 8-10. Input Capture Registers (ICRH and ICRL)

**NOTE**

To prevent interrupts from occurring between readings of ICRH and ICRL, set the interrupt flag in the condition code register before reading ICRH, and clear the flag after reading ICRL.

**8.2.6 Output Compare Registers (OCRH and OCRL)**

When the value of the 16-bit counter matches the value in the output compare registers, the planned TCMP pin action occurs. Writing to OCRH before writing to OCRL inhibits timer compares until OCRL is written. Reading or writing to OCRL after reading the timer status register clears the output compare flag (OCF).

**OCRH and OCRL — Output Compare Registers High/Low \$0016 and \$0017**

\$0016	Bit 15	14	13	12	11	10	9	Bit 8
\$0017	Bit 7	6	5	4	3	2	1	Bit 0

Reset does not affect the output compare registers.

**Figure 8-11. Output Compare Registers (OCRH and OCRL)**

To prevent OCF from being set between the time it is read and the time the output compare registers are updated, use the following procedure:

1. Disable interrupts by setting the I bit in the condition code register.
2. Write to OCRH. Compares are now inhibited until OCRL is written.
3. Clear bit OCF by reading the timer status register (TSR).
4. Enable the output compare function by writing to OCRL.
5. Enable interrupts by clearing the I bit in the condition code register.

## **SECTION 9 SERIAL COMMUNICATIONS INTERFACE**

This section describes the on-chip asynchronous serial communications interface (SCI).

### **9.1 Features**

Features of the SCI include the following:

- Standard Mark/Space Non-Return-to-Zero Format
- Full Duplex Operation
- 32 Programmable Baud Rates
- Programmable 8-bit or 9-bit Character Length
- Separately Enabled Transmitter and Receiver
- Two Receiver Wakeup Methods:
  - Idle Line Wakeup
  - Address Mark Wakeup
- Interrupt-Driven Operation Capability with Five Interrupt Flags:
  - Transmitter Data Register Empty
  - Transmission Complete
  - Receiver Data Register Full
  - Receiver Overrun
  - Idle Receiver Input
- Receiver Framing Error Detection
- 1/16 Bit-Time Noise Detection

## 9.2 SCI Data Format

The SCI uses the standard non-return-to-zero mark/space data format illustrated in Figure 9-1.

**Figure 9-1. SCI Data Format**

## 9.3 SCI Operation

The SCI allows full-duplex, asynchronous, RS232 or RS422 serial communication between the MCU and remote devices, including other MCUs. The transmitter and receiver of the SCI operate independently, although they use the same baud rate generator. The following paragraphs describe the operation of the SCI transmitter and receiver.

### 9.3.1 Transmitter

Figure 9-2 shows the structure of the SCI transmitter.

#### 9.3.1.1 Character Length

The transmitter can accommodate either 8-bit or 9-bit data. The state of the M bit in SCI control register 1 (SCCR1) determines character length. When transmitting 9-bit data, bit T8 in SCCR1 is the ninth bit (bit 8).

#### 9.3.1.2 Character Transmission

During transmission, the transmit shift register shifts a character out to the PD1/TDO pin. The SCI data register (SCDR) is the write-only buffer between the internal data bus and the transmit shift register.

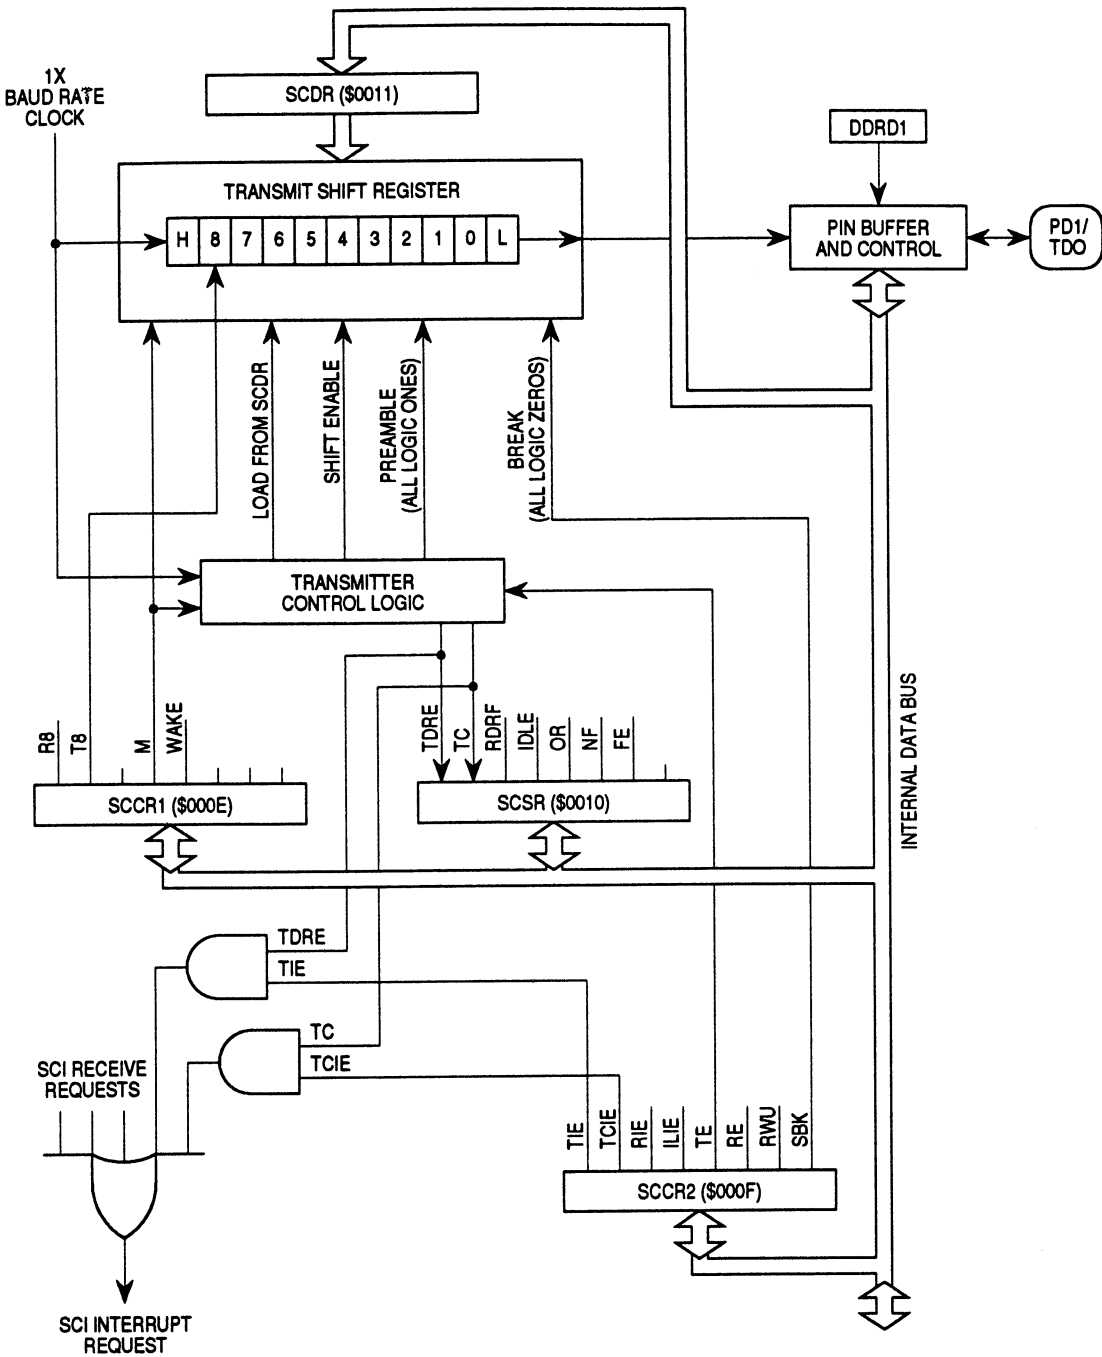

Figure 9-2. SCI Transmitter

Writing a logic one to the TE bit in SCI control register 2 (SCCR2) and then writing data to the SCDR begins the transmission. At the start of a transmission, transmitter control logic automatically loads the transmit shift register with a preamble of logic ones. After the preamble shifts out, the control logic transfers the SCDR data into the shift register. A logic zero start bit automatically goes into the least significant bit position of the shift register, and a logic one stop bit goes into the most significant bit position.

When the data in the SCDR transfers to the transmit shift register, the TDRE flag in the SCI status register (SCSR) becomes set. The TDRE flag indicates that the SCDR can accept new data from the internal data bus.

When the shift register is not transmitting a character, the PD1/TDO pin goes to the idle condition, logic one. If software clears the TE bit during the idle condition, and while TDRE is set, the transmitter relinquishes control of the PD1/TDO pin.

#### 9.3.1.3 Break Characters

Writing a logic one to the SBK bit in SCCR2 loads the shift register with a break character. A break character contains all logic zeros and has no start and stop bits. Break character length depends on the M bit in SCCR1. As long as SBK is at logic one, transmitter logic continuously loads break characters into the shift register. After software clears the SBK bit, the shift register finishes transmitting the last break character and then transmits at least one logic one. The automatic logic one at the end of a break character is to guarantee the recognition of the start bit of the next character.

#### 9.3.1.4 Idle Characters

An idle character contains all logic ones and has no start or stop bits. Idle character length depends on the M bit in SCCR1. The preamble is a synchronizing idle character that begins every transmission.

Clearing the TE bit during a transmission relinquishes the PD1/TDO pin after the last character to be transmitted is shifted out. The last character may already be in the shift register, or waiting in the SCDR, or it may be a break character generated by writing to the SBK bit. Toggling TE from logic zero to logic one while the last character is in transmission generates an idle character (a preamble) that allows the receiver to maintain control of the PD1/TDO pin.

### 9.3.1.5 Transmitter Interrupts

The following sources can generate transmitter interrupt requests:

- Transmit Data Register Empty (TDRE) — The TDRE bit in the SCSR indicates that the SCDR has transferred a character to the transmit shift register.
- Transmission Complete (TC) — The TC bit in the SCSR indicates that both the transmit shift register and the SCDR are empty and that no break or idle character has been generated.

### 9.3.2 Receiver

Figure 9-3 shows the structure of the SCI receiver.

#### 9.3.2.1 Character Length

The receiver can accommodate either 8-bit or 9-bit data. The state of the M bit in SCI control register 1 (SCCR1) determines character length. When receiving 9-bit data, bit R8 in SCCR1 is the ninth bit (bit 8).

#### 9.3.2.2 Character Reception

During reception, the receive shift register shifts characters in from the PD0/RDI pin. The SCI data register (SCDR) is the read-only buffer between the internal data bus and the receive shift register.

After a complete character shifts into the receive shift register, the data portion of the character is transferred to the SCDR, setting the RDRF flag. The RDRF flag can be used to generate an interrupt.

#### 9.3.2.3 Receiver Wakeup

So that the MCU can ignore transmissions intended only for other receivers in multiple-receiver systems, the MCU can be put into a standby state. Setting the RWU bit in SCI control register 2 (SCCR2) puts the MCU into a standby state during which receiver interrupts are disabled.

Figure 9-3. SCI Receiver

Either of two conditions on the PD0/RDI pin can bring the MCU out of the standby state:

- Idle input line condition — If the PD0/RDI pin is at logic one long enough for 10 or 11 logic ones to shift into the receive shift register, receiver interrupts are again enabled.
- Address mark — If a logic one occurs in the most significant bit position of a received character, receiver interrupts are again enabled.

The state of the WAKE bit in SCCR1 determines which of the two conditions wakes up the MCU.

#### 9.3.2.4 Receiver Noise Immunity

The data recovery logic samples each bit 16 times to identify and verify the start bit and to detect noise. Any conflict between noise-detection samples sets the NF flag in the SCSR. The NF flag is set at the same time that the RDRF flag is set.

#### 9.3.2.5 Framing Errors

If the data recovery logic does not detect a logic one where the stop bit should be in an incoming character, it sets the FE flag in the SCSR. The FE flag is set at the same time that the RDRF flag is set.

#### 9.3.2.6 Receiver Interrupts

The following sources can generate receiver interrupt requests:

- Receive Data Register Full (RDRF) — The RDRF flag in the SCSR indicates that the receive shift register has transferred a character to the SCDR.
- Receiver Overrun (OR) — The OR flag in the SCSR indicates that the receive shift register shifted in a new character before the previous character was read from the SCDR.
- Idle Input (IDLE) — The IDLE flag in the SCSR indicates that 10 or 11 consecutive logic ones shifted in from the PD0/RDI pin.

## 9.4 SCI I/O Registers

The following I/O registers control and monitor SCI operation:

- SCI Data Register (SCDR)
- SCI Control Register 1 (SCCR1)
- SCI Control Register 2 (SCCR2)
- SCI Status Register (SCSR)

### 9.4.1 SCI Data Register (SCDR)

The SCI data register, shown in Figure 9-4, is the buffer for characters received and for characters transmitted.

**Figure 9-4. SCI Data Register (SCDR)**

### 9.4.2 SCI Control Register 1 (SCCR1)

SCI control register 1, shown in Figure 9-5, has the following functions:

- Stores ninth SCI data bit received and ninth SCI data bit transmitted
- Controls SCI character length
- Controls SCI wakeup method

**SCCR1 — SCI Control Register 1**

**\$000E**

	Bit 7	6	5	4	3	2	1	Bit 0
	R8	T8	—	M	WAKE	—	—	—
RESET:	U	U	0	U	U	0	0	0

U = UNAFFECTED

**Figure 9-5. SCI Control Register 1 (SCCR1)**

**R8 — Bit 8 (Received)**

When the SCI is receiving 9-bit characters, R8 is the ninth bit of the received character. R8 receives the ninth bit at the same time that the SCDR receives the other eight bits. Resets have no effect on the R8 bit.

**T8 — Bit 8 (Transmitted)**

When the SCI is transmitting 9-bit characters, T8 is the ninth bit of the transmitted character. T8 is loaded into the transmit shift register at the same time that SCDR is loaded into the transmit shift register. Resets have no effect on the T8 bit.

**M — Character Length**

This read/write bit determines whether SCI characters are 8 bits long or 9 bits long. The ninth bit can be used as an extra stop bit, as a receiver wakeup signal, or as a mark or space parity bit. Resets have no effect on the M bit.

- 1 = 9-bit SCI characters
- 0 = 8-bit SCI characters

**WAKE — Wakeup Method**

This read/write bit determines which condition wakes up the SCI: a logic one (address mark) in the most significant bit (MSB) position of a received character or an idle condition on the PD0/RDI pin. Resets have no effect on the WAKE bit.

- 1 = Address mark wakeup
- 0 = Idle line wakeup

### 9.4.3 SCI Control Register 2 (SCCR2)

SCI control register 2, shown in Figure 9-6, has the following functions:

- Enables the SCI receiver and SCI receiver interrupts
- Enables the SCI transmitter and SCI transmitter interrupts
- Enables SCI receiver idle interrupts
- Enables SCI transmission complete interrupts
- Enables SCI wakeup
- Transmits SCI break characters

**SCCR2 — SCI Control Register 2** **\$000F**

	Bit 7	6	5	4	3	2	1	Bit 0
	TIE	TCIE	RIE	ILIE	TE	RE	RWU	SBK
RESET:	0	0	0	0	0	0	0	0

**Figure 9-6. SCI Control Register 2 (SCCR2)**

**TIE — Transmit Interrupt Enable**

This read/write bit enables SCI interrupt requests when the TDRE flag becomes set. Resets clear the TIE bit.

- 1 = TDRE interrupt requests enabled
- 0 = TDRE interrupt requests disabled

**TCIE — Transmission Complete Interrupt Enable**

This read/write bit enables SCI interrupt requests when the TC flag becomes set. Resets clear the TCIE bit.

- 1 = TC interrupt requests enabled
- 0 = TC interrupt requests disabled

**RIE — Receive Interrupt Enable**

This read/write bit enables SCI interrupt requests when the RDRF flag or the OR flag becomes set. Resets clear the RIE bit.

- 1 = RDRF interrupt requests enabled
- 0 = RDRF interrupt requests disabled

**ILIE — Idle Line Interrupt Enable**

This read/write bit enables SCI interrupt requests when the IDLE bit becomes set. Resets clear the ILIE bit.

- 1 = IDLE interrupt requests enabled
- 0 = IDLE interrupt requests disabled

**TE — Transmit Enable**

Setting this read/write bit begins the transmission by sending a preamble of 10 or 11 logic ones from the transmit shift register to the PD1/TDO pin. Resets clear the TE bit.

- 1 = Transmission enabled
- 0 = Transmission disabled

**RE — Receive Enable**

Setting this read/write bit enables the receiver. Clearing the RE bit disables the receiver and receiver interrupts but does not affect the receiver interrupt flags. Resets clear the RE bit.

- 1 = Receiver enabled
- 0 = Receiver disabled

**RWU — Receiver Wakeup Enable**

This read/write bit puts the receiver in a standby state. Typically, data transmitted to the receiver clears the RWU bit and returns the receiver to normal operation. The WAKE bit in SCCR1 determines whether an idle input or an address mark brings the receiver out of the standby state. Resets clear the RWU bit.

- 1 = Standby state
- 0 = Normal operation

**SBK — Send Break**

Setting this read/write bit continuously transmits break codes in the form of 10-bit or 11-bit groups of logic zeros. Clearing the SBK bit stops the break codes and transmits a logic one as a start bit. Resets clear the SBK bit.

- 1 = Break codes being transmitted
- 0 = No break codes being transmitted

### 9.4.4 SCI Status Register (SCSR)

The SCI status register, shown in Figure 9-7, contains flags to signal the following conditions:

- Transfer of SCDR data to transmit shift register complete
- Transmission complete
- Transfer of receive shift register data to SCDR complete
- Receiver input idle
- Receiver overrun
- Noisy data
- Framing error

**SCSR — SCI Status Register (SCSR) \$0010**

	Bit 7	6	5	4	3	2	1	Bit 0
	TDRE	TC	RDRF	IDLE	OR	NF	FE	—
RESET:	1	1	0	0	0	0	0	—

**Figure 9-7. SCI Status Register (SCSR)**

#### TDRE — Transmit Data Register Empty

This clearable, read-only flag is set when the data in the SCDR transfers to the transmit shift register. TDRE generates an interrupt request if the TIE bit in SCCR2 is also set. Clear the TDRE bit by reading the SCSR with TDRE set, and then writing to the SCDR. Resets set the TDRE bit. Software must initialize the TDRE bit to logic zero to avoid an instant interrupt request when turning the transmitter on.

- 1 = SCDR data transferred to transmit shift register
- 0 = SCDR data not transferred to transmit shift register

**TC — Transmission Complete**

This clearable, read-only flag is set when the TDRE bit is set, and no data, preamble, or break character is being transmitted. TC generates an interrupt request if the TCIE bit in SCCR2 is also set. Clear the TC bit by reading the SCSR with TC set, and then writing to the SCDR. Resets set the TC bit. Software must initialize the TC bit to logic zero to avoid an instant interrupt request when turning the transmitter on.

- 1 = No transmission in progress
- 0 = Transmission in progress

**RDRF — Receive Data Register Full**

This clearable, read-only flag is set when the data in the receive shift register transfers to the SCI data register. RDRF generates an interrupt request if the RIE bit in SCCR2 is also set. Clear the RDRF bit by reading the SCSR with RDRF set, and then reading the SCDR.

- 1 = Received data available in SCDR
- 0 = Received data not available in SCDR

**IDLE — Receiver Idle**

This clearable, read-only flag is set when 10 or 11 consecutive logic ones appear on the receiver input. IDLE generates an interrupt request if the ILIE bit in SCCR2 is also set. Clear the IDLE bit by reading the SCSR with IDLE set, and then reading the SCDR.

- 1 = Receiver input idle
- 0 = Receiver input not idle

**OR — Receiver Overrun**

This clearable, read-only flag is set if the SCDR is not read before the receive shift register receives the next word. OR generates an interrupt request if the RIE bit in SCCR2 is also set. The data in the shift register is lost, but the data already in the SCDR is not affected. Clear the OR bit by reading the SCSR with OR set, and then reading the SCDR.

- 1 = Receive shift register full and RDRF = 1
- 0 = No receiver overrun

**NF — Receiver Noise Flag**

This clearable, read-only flag is set when noise is detected in data received in the SCI data register. Clear the NF bit by reading the SCSR, and then reading the SCDR.

- 1 = Noise detected in SCDR
- 0 = No noise detected in SCDR

**FE — Receiver Framing Error**

This clearable, read-only flag is set when there is a logic zero where a stop bit should be in the character shifted into the receive shift register. If the received word causes both a framing error and an overrun error, the OR flag is set and the FE flag is not set. Clear the FE bit by reading the SCSR, and then reading the SCDR.

- 1 = Framing error
- 0 = No framing error

**9.4.5 Baud Rate Register (BAUD)**

The baud rate register, shown in Figure 9-8, selects the baud rate for both the receiver and the transmitter.

**BAUD — Baud Rate Register** **\$000D**

	Bit 7	6	5	4	3	2	1	Bit 0
	—	—	SCP1	SCP0	—	SCR2	SCR1	SCR0
RESET:	—	—	0	0	—	U	U	U

**Figure 9-8. Baud Rate Register (BAUD)**

**SCP1 and SCP0 — SCI Prescaler Select Bits**

These read/write bits control prescaling of the baud rate generator clock, as shown in Table 9-1. Resets clear both SCP1 and SCP0.

**Table 9-1. Baud Rate Generator Clock Prescaling**

SCP[1:0]	Baud Rate Generator Clock
00	Internal Clock + 1
01	Internal Clock + 3
10	Internal Clock + 4
11	Internal Clock + 13

**SCR2–SCR0 — SCI Baud Rate Select Bits**

These read/write bits select the SCI baud rate, as shown in Table 9-2. Resets have no effect on the SCR2–SCR0 bits.

**Table 9-2. Baud Rate Selection**

SCR[2:1:0]	SCI Baud Rate (Baud)
000	Prescaled Clock + 1
001	Prescaled Clock + 2
010	Prescaled Clock + 4
011	Prescaled Clock + 8
100	Prescaled Clock + 16
101	Prescaled Clock + 32
110	Prescaled Clock + 64
111	Prescaled Clock + 128

Table 9-3 shows all possible SCI baud rates derived from crystal frequencies of 2 MHz, 4 MHz, and 4.194304 MHz.

**Table 9-3. Baud Rate Select Examples**

SCP[1:0]	SCR[2:1:0]	SCI Baud Rate		
		fosc = 2 MHz	fosc = 4 Mhz	fosc = 4.194304 MHz
00	000	62.50 kbaud	125 kbaud	131.1 kbaud
00	001	31.25 kbaud	62.50 kbaud	65.54 kbaud
00	010	15.63 kbaud	31.25 kbaud	32.77 kbaud
00	011	7813 Baud	15.63 kbaud	16.38 kbaud
00	100	3906 Baud	7813 Baud	8192 Baud
00	101	1953 Baud	3906 Baud	4096 Baud

01	011	2604 Baud	5208 Baud	5461 Baud
01	100	1302 Baud	2604 Baud	2731 Baud
01	101	651.0 Baud	1302 Baud	1365 Baud
01	110	325.5 Baud	651.0 Baud	682.7 Baud
01	111	162.8 Baud	325.5 Baud	341.3 Baud
10	000	15.63 kbaud	31.25 kbaud	32.77 kbaud
10	001	7813 Baud	15.63 kbaud	16.38 kbaud
10	010	3906 Baud	7813 Baud	8192 Baud
10	011	1953 Baud	3906 Baud	4096 Baud
10	100	976.6 Baud	1953 Baud	2048 Baud
10	101	488.3 Baud	976.6 Baud	1024 Baud
10	110	244.1 Baud	488.3 Baud	512.0 Baud
10	111	122.1 Baud	244.1 Baud	256.0 Baud
11	000	4808 Baud	9615 Baud	10.08 kbaud
11	001	2404 Baud	4808 Baud	5041 Baud
11	010	1202 Baud	2404 Baud	2521 Baud
11	011	601.0 Baud	1202 Baud	1260 Baud
11	100	300.5 Baud	601.0 Baud	630.2 Baud
11	101	150.2 Baud	300.5 Baud	315.1 Baud
11	110	75.12 Baud	150.2 Baud	157.5 Baud
11	111	37.56 Baud	75.12 Baud	78.77 Baud

## SECTION 10 SERIAL PERIPHERAL INTERFACE

This section describes the on-chip, synchronous, serial peripheral interface (SPI).

### 10.1 Features

Features of the SPI include the following:

- Full Duplex Operation
- Master and Slave Modes
- Four Programmable Master Mode Frequencies (1.05-MHz Maximum)
- 2.1-MHz Maximum Slave Mode Frequency
- Serial Clock with Programmable Polarity and Phase
- End of Transmission Interrupt Flag
- Write Collision Protection
- Bus Contention Protection

Figure 10-1 shows the structure of the SPI subsystem.

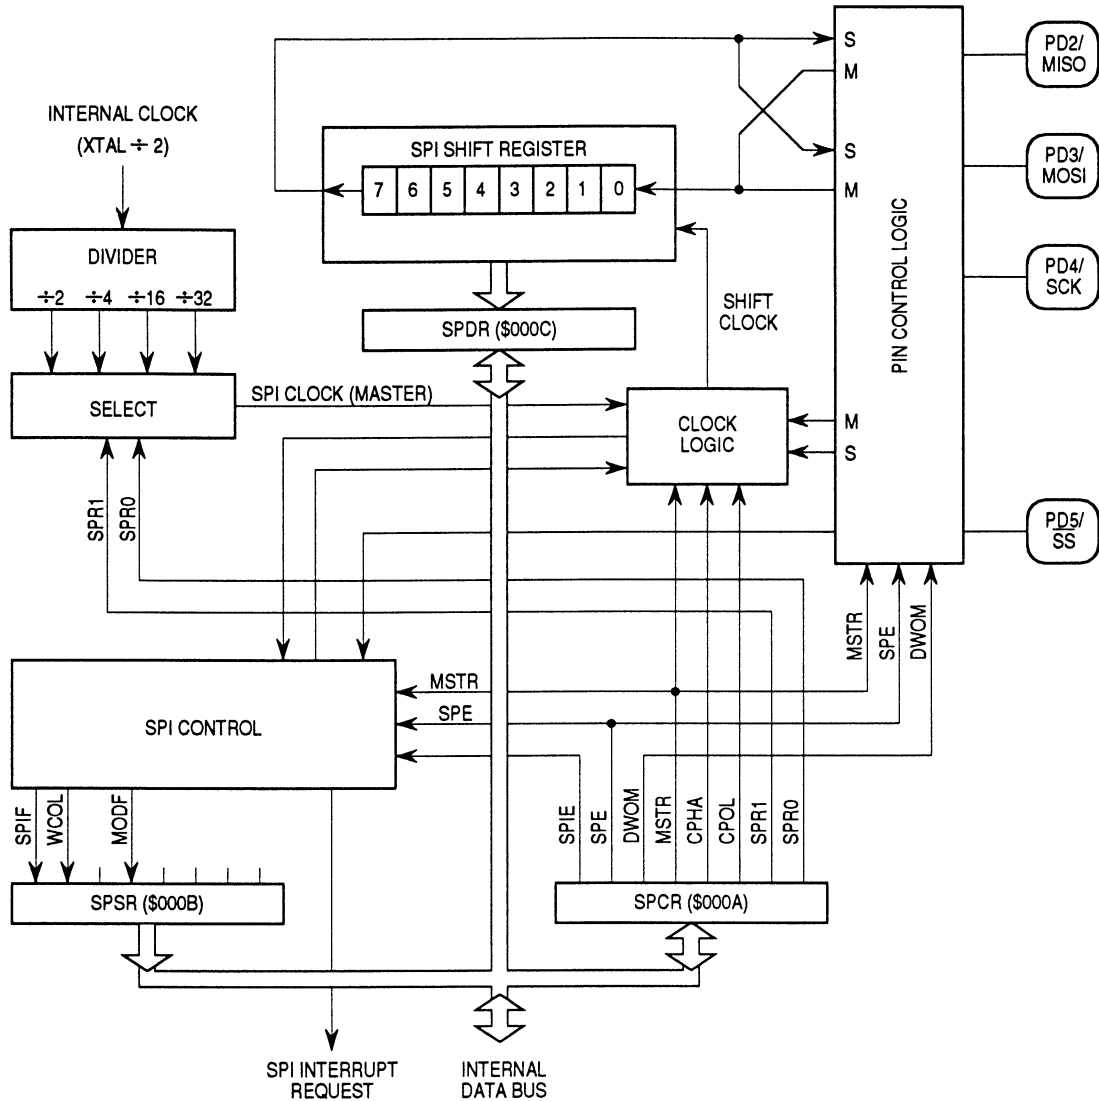

Figure 10-1. SPI Block Diagram

## 10.2 Operation

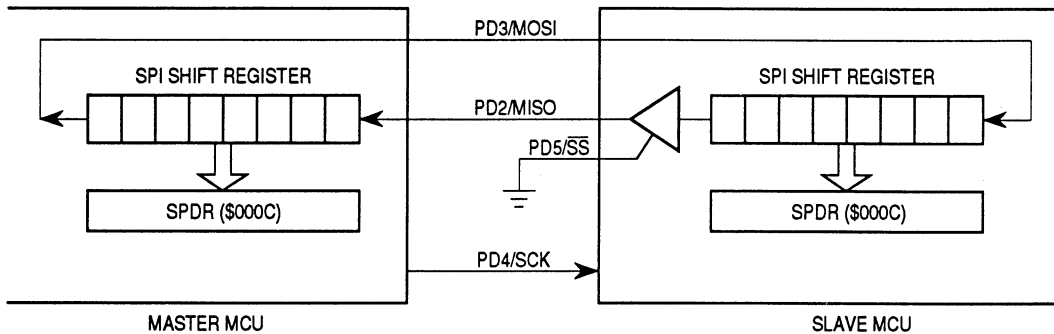

The master/slave SPI allows full-duplex, synchronous, serial communication between the MCU and peripheral devices, including other MCUs. As the 8-bit shift register of a master SPI transmits each byte to another device, a byte from the receiving device can enter the master SPI shift register. A clock signal from the master SPI synchronizes data transmission.

Only a master SPI can initiate transmissions. Software begins the transmission from a master SPI by writing to the SPI data register (SPDR). The SPDR does not buffer data being transmitted from the SPI. Data written to the SPDR goes directly into the shift register and begins the transmission immediately under the control of the serial clock. The transmission ends after eight cycles of the serial clock when the SPI flag (SPIF) in the SPI status register (SPSR) becomes set. At the same time that SPIF becomes set, the data shifted into the master SPI from the receiving device transfers to the SPDR. The SPDR buffers data being received by the SPI. Before the master SPI sends the next byte, software must clear the SPIF bit by reading the SPSR and then accessing the SPDR.

In a slave SPI, data enters the shift register under the control of the serial clock from the master SPI. After a byte enters the shift register of a slave SPI, it transfers to the SPDR. To prevent an overrun condition, slave software must then read the byte in the SPDR before another byte enters the shift register and is ready to transfer to the SPDR.

Figure 10-2 shows how a master SPI exchanges data with a slave SPI.

**Figure 10-2. Master/Slave Connections**

### 10.2.1 Pin Functions in Master Mode

Setting the MSTR bit in the SPI control register (SPCR) configures the SPI for operation in master mode. The following paragraphs describe the master-mode functions of the SPI pins.

#### 10.2.1.1 PD4/SCK (Serial Clock)

In master mode, the PD4/SCK pin is the synchronizing clock output.

#### 10.2.1.2 PD3/MOSI (Master Output, Slave Input)

In master mode, the PD3/MOSI pin is the serial output.

#### 10.2.1.3 PD2/MISO (Master Input, Slave Output)

In master mode, the PD2/MISO pin is configured as the serial input.

#### 10.2.1.4 PD5/ $\overline{SS}$ (Slave Select)

In master mode, the PD5/ $\overline{SS}$  pin performs a mode-fault detection function. To protect against driver contention caused by the simultaneous operation of two SPIs in master mode, the master SPI monitors the PD5/ $\overline{SS}$  pin for a logic zero. A logic zero on the PD5/ $\overline{SS}$  pin of a master SPI disables the SPI, clears the MSTR bit, and sets the mode-fault flag (MODF).

### 10.2.2 Pin Functions in Slave Mode

Clearing the MSTR bit in the SPCR configures the SPI for operation in slave mode. The following paragraphs describe the slave-mode functions of the SPI pins.

#### 10.2.2.1 PD4/SCK (Serial Clock)

In slave mode, the PD4/SCK pin is the input for the synchronizing clock signal from the master SPI.

#### 10.2.2.2 PD3/MOSI (Master Output, Slave Input)

In slave mode, the PD3/MOSI pin is the serial input.

#### 10.2.2.3 PD2/MISO (Master Input, Slave Output)

In slave mode, the PD2/MISO pin is the serial output. The MISO line of a slave device is placed in a high-impedance state if slave is not selected ( $\overline{SS} = 1$ ).

#### 10.2.2.4 PD5/ $\overline{SS}$ (Slave Select)

In slave mode, the PD5/ $\overline{SS}$  pin enables the SPI for data and serial clock reception from a master SPI.

When CPHA = 0, the shift clock is the OR of  $\overline{SS}$  with SCK. In this clock phase mode,  $\overline{SS}$  must go high between successive characters in an SPI message. When CPHA = 1,  $\overline{SS}$  may be left low for several SPI characters. In cases where there is only one SPI slave MCU, the slave MCU  $\overline{SS}$  line can be tied to  $V_{SS}$  as long as CPHA = 1 clock modes are used.

### 10.3 Multiple-SPI Systems

In a multiple-SPI system, all PD4/SCK pins are connected together, all PD3/MOSI pins are connected together, and all PD2/MISO pins are connected together.

Before a transmission, one SPI is configured as master and the rest are configured as slaves. Figure 10-3 is a block diagram showing a single master SPI and three slave SPIs.

Figure 10-3. One Master and Three Slaves Block Diagram

Figure 10-4 is another block diagram with two master/slave SPIs and three slave SPIs.

Figure 10-4. Two Master/Slaves and Three Slaves Block Diagram

### 10.4 Serial Clock Polarity and Phase

To accommodate the different serial communication requirements of peripheral devices, software can change the phase and polarity of the SPI serial clock. The clock polarity bit (CPOL) and the clock phase bit (CPHA), both in the SPCR, control the timing relationship between the serial clock and the transmitted data. Figure 10-5 shows how the CPOL and CPHA bits affect the clock/data timing.

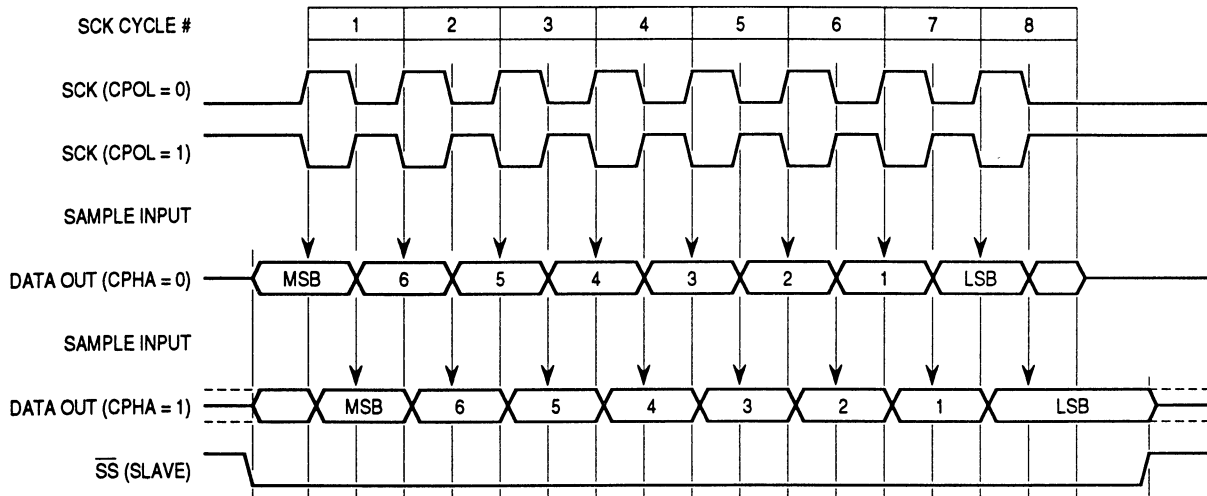

Figure 10-5. SPI Clock/Data Timing

## 10.5 SPI Error Conditions

The following conditions produce SPI system error conditions:

- Bus contention caused by multiple master SPIs (mode-fault error)
- Writing to the SPDR during a transmission (write-collision error)
- Failing to read the SPDR before the next incoming byte sets the SPIF bit (overflow error)

### 10.5.1 Mode-Fault Error

A mode-fault error happens when a logic zero occurs on the PD5/ $\overline{SS}$  pin of a master SPI. The MCU takes the following actions when a mode-fault error happens:

- Sets the MODF bit; generates an SPI interrupt if SPIE = 1
- Disables the SPI by clearing the SPE bit
- Puts the SPI in slave mode by clearing the MSTR bit

### 10.5.2 Write-Collision Error

Writing to the SPDR during a transmission causes a write-collision error and sets the WCOL bit in the SPSR. Either a master SPI or a slave SPI can generate a write-collision error.

- Master — A master SPI can cause a write-collision error by writing to the SPDR while the previously written byte is still being shifted out to the PD3/MOSI pin. The error does not affect the transmission of the previously written byte, but the byte that caused the error is lost.
- Slave — A slave SPI can cause a write-collision error in either of two ways, depending on the state of the CPHA bit:
  - a) CPHA = 0 — A slave SPI can cause a write-collision error by writing to the SPDR while the PD5/ $\overline{SS}$  pin is at logic zero. The error does not affect the byte in the SPDR, but the byte that caused the error is lost.

- b) CPHA = 1 — A slave SPI can cause a write-collision error by writing to the SPDR while receiving a transmission, that is, between the first active SCK edge and the end of the eighth SCK cycle. The error does not affect the transmission from the master SPI, but the byte that caused the error is lost.

### 10.5.3 Overflow Error

Failing to read the byte in the SPDR before a subsequent byte enters the shift register causes an overflow condition. In an overflow condition, all incoming data is lost until software clears SPIF. There is no flag for the overflow condition.

## 10.6 SPI Interrupts

The SPIF bit in the SPSR indicates a byte has shifted into or out of the SPDR. The SPIF bit is a source of SPI interrupt requests. The SPI interrupt enable bit (SPIE) in the SPCR is the local mask for SPIF interrupts.

The MODF bit in the SPSR indicates a mode error and is a source of SPI interrupt requests. The MODF bit is set when a logic zero occurs on the PD5/ $\overline{SS}$  pin while the MSTR bit is set. The SPI interrupt enable bit (SPIE) in the SPCR is the local mask for MODF interrupts.

## 10.7 SPI I/O Registers

The following I/O registers control and monitor SPI operation:

- SPI Data Register (SPDR)
- SPI Control Register (SPCR)
- SPI Status Register (SPSR)

### 10.7.1 SPI Data Register (SPDR)

The SPDR, shown in Figure 10-6, is the read buffer for characters received by the SPI. Writing a byte to the SPDR places the byte directly into the SPI shift register.

**SPDR — SPI Data Register**

**\$000C**

**Figure 10-6. SPI Data Register (SPDR)**

**10.7.2 SPI Control Register (SPCR)**

The SPCR, shown in Figure 10-7, has the following functions:

- Enables SPI interrupt requests
- Enables the SPI
- Configures port D pins as open-drain outputs
- Configures the SPI as master or slave
- Selects serial clock polarity, phase, and frequency

**SPCR — SPI Control Register**

**\$000A**

**Figure 10-7. SPI Control Register (SPCR)**

**SPIE — SPI Interrupt Enable**

This read/write bit enables SPI interrupts. Resets clear the SPIE bit.

- 1 = SPI interrupts enabled
- 0 = SPI interrupts disabled

**SPE — SPI Enable**

This read/write bit enables the SPI. Resets clear the SPE bit.

- 1 = SPI enabled
- 0 = SPI disabled

Bit 5 — Not used; reads either one or zero

**MSTR — Master**

This read/write bit selects master mode operation or slave mode operation.

Resets clear the MSTR bit.

- 1 = Master mode
- 0 = Slave mode

**CPOL — Clock Polarity**

This read/write bit determines the logic state of the PD4/SCK pin between transmissions. To transmit data between SPIs, the SPIs must have identical CPOL bits. Resets have no effect on the CPOL bit.

- 1 = PD4/SCK pin at logic one between transmissions
- 0 = PD4/SCK pin at logic zero between transmissions

**CPHA — Clock Phase**

This read/write bit controls the timing relationship between the serial clock and SPI data. To transmit data between SPIs, the SPIs must have identical CPHA bits. When CPHA = 0, the PD5/ $\overline{SS}$  pin of the slave SPI must be set to logic one between bytes. (See Figure 10-5.) Reset has no effect on the CPHA bit.

- 1 = Edge following first active edge on PD4/SCK latches data
- 0 = First active edge on PD4/SCK latches data

**SPR1 and SPR0 — SPI Clock Rate**

These read/write bits select master mode serial clock rate, as shown in Table 10-1. The SPR1 and SPR0 bits of a slave SPI have no effect on the serial clock.

**Table 10-1. SPI Clock Rate Selection**

SPR[1:0]	SPI Clock Rate
00	Internal Clock ÷ 2
01	Internal Clock ÷ 4
10	Internal Clock ÷ 16
11	Internal Clock ÷ 32

### 10.7.3 SPI Status Register (SPSR)

The SPSR, shown in Figure 10-8, contains flags to signal the following conditions:

- SPI transmission complete
- Write collision
- Mode fault

**SPSR** — SPI Status Register

**\$000B**

	Bit 7	6	5	4	3	2	1	Bit 0
	SPIF	WCOL	—	MODF	—	—	—	—
RESET:	0	0	0	0	—	—	—	—

**Figure 10-8. SPI Status Register (SPSR)**

#### SPIF — SPI Flag

This clearable, read-only flag is set each time a byte shifts out of or into the shift register. SPIF generates an interrupt request if the SPIE bit in the SPCR is also set. Clear the SPIF bit by reading the SPSR with SPIF set, and then reading or writing the SPDR. Resets clear the SPIF bit.

- 1 = Transmission complete
- 0 = Transmission not complete

#### WCOL — Write Collision

This clearable, read-only flag is set when software writes to the SPDR while a transmission is in progress. Clear the WCOL flag by reading the SPSR with WCOL set, and then reading or writing the SPDR. Resets clear the WCOL flag.

- 1 = Invalid write to SPDR
- 0 = No invalid write to SPDR

#### MODF — Mode Fault

This clearable, read-only flag is set when a logic zero occurs on the PD5/ $\overline{SS}$  pin while the MSTR bit is set. MODF generates an interrupt request if the SPIE bit is also set. Clear the MODF flag by reading the SPSR with MODF set, and then writing the SPCR. Resets clear the MODF flag.

- 1 = PD5/ $\overline{SS}$  pulled low while MSTR bit set
- 0 = PD5/ $\overline{SS}$  not pulled low while MSTR bit set

**SECTION 11  
SELF-CHECK ROM**

This section describes how to use the self-check ROM to test the MCU.

**11.1 Self-Check Tests**

The self-check ROM at mask ROM location \$3F00–\$3FEF determines if the MCU is functioning properly. The following tests are performed:

1. I/O — Functional test of ports A, B, and C
2. RAM — Counter test for each RAM byte
3. Timer — Test of counter register and OCF bit
4. SCI — Transmission test: checks for RDRF, TDRE, TC, and FE flags
5. ROM — Exclusive OR with odd ones parity result
6. SPI — Transmission test: checks for SPIF, WCOL, and MODF flags

The self-check circuit is shown in Figure 11-1.

**11.2 Self-Check Results**

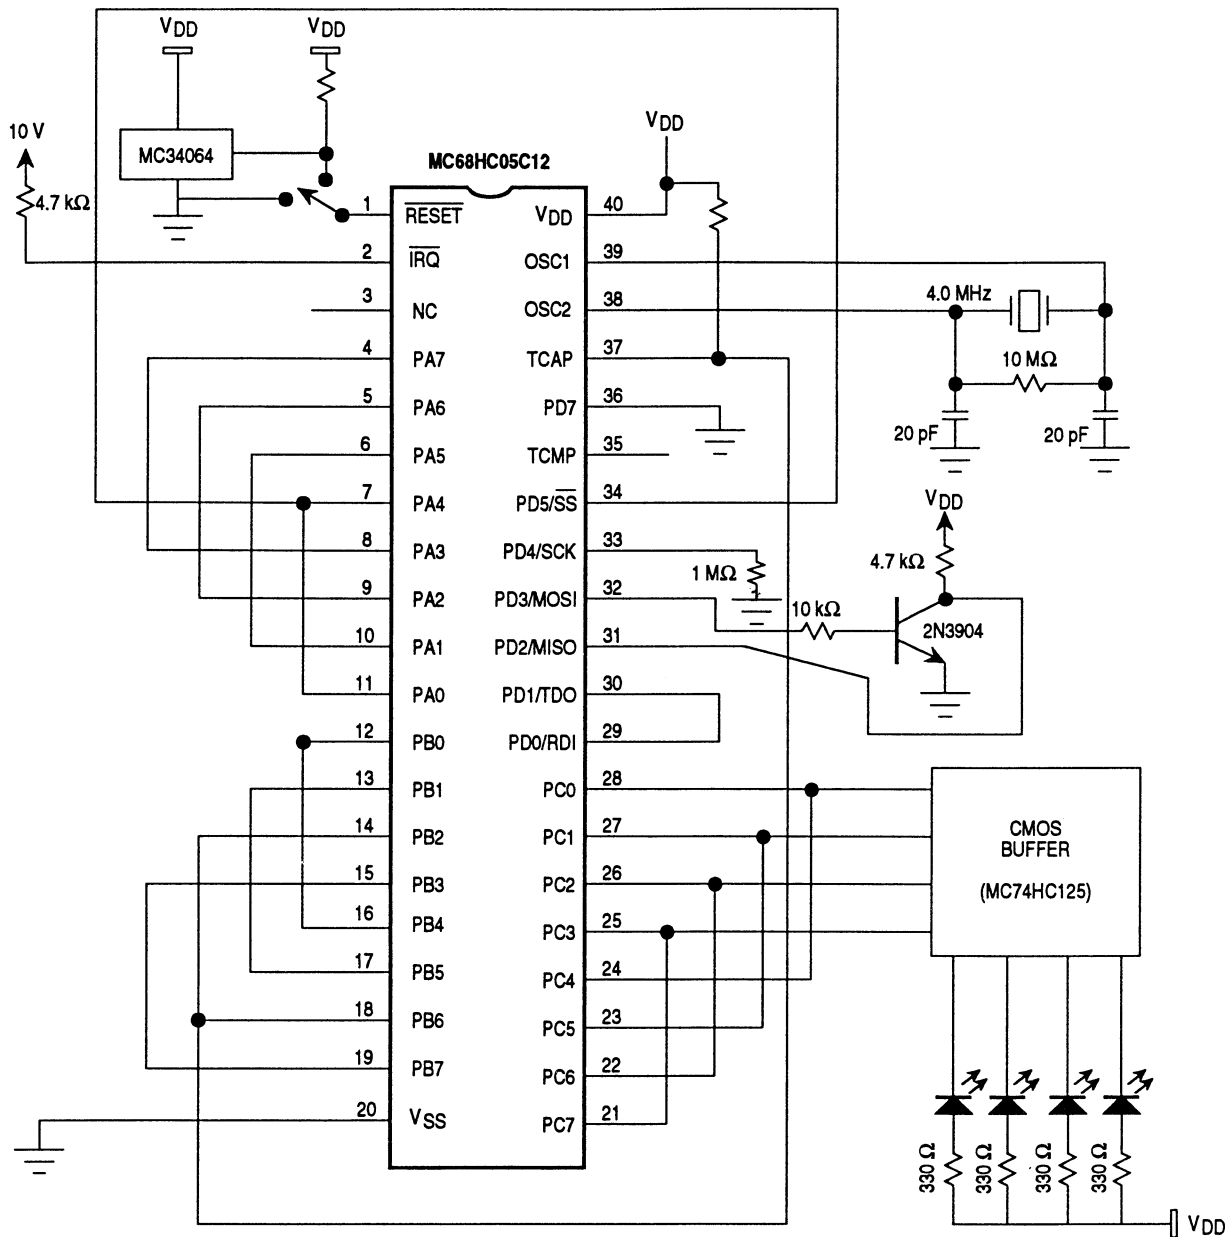

Table 11-1 shows the LED codes that indicate self-check test results.

**Table 11-1. Self-Check Circuit LED Codes**

PC3	PC2	PC1	PC0	Remarks
Off	On	On	Off	I/O Failure
Off	On	Off	On	RAM Failure
Off	On	Off	Off	Timer Failure
Off	Off	On	On	SCI Failure
Off	Off	On	Off	ROM Failure
Off	Off	Off	On	SPI Failure
Flashing				No Failures
All Others				Device Failure

### 11.3 Self-Check Circuit

Figure 11-1 shows the self-check circuit.

NOTES:

1.  $V_{DD} = 5.0\text{ V}$
2. TCMP = NC

Figure 11-1. Self-Check Circuit Schematic

Perform the following steps to activate the self-check tests:

1. Apply 10 V ( $2 \times V_{DD}$ ) to the  $\overline{IRQ}$  pin.
2. Apply a logic one to the TCAP pin.
3. Apply a logic zero to the  $\overline{RESET}$  pin.

The self-check tests begin on the rising edge of the  $\overline{RESET}$  pin.

$\overline{RESET}$  must be held low for 4064 cycles after power-on reset (POR), or for a time,  $t_{RL}$ , for any other reset. (For the  $t_{RL}$  value see **Table 13.6 Control Timing ( $V_{DD} = 5.0$  Vdc).**)

The COP watchdog (a mask optional feature) is disabled by hardware during self-check mode.

## SECTION 12 INSTRUCTION SET

This section describes the addressing modes and the types of instructions.

### 12.1 Addressing Modes

The CPU uses eight addressing modes for flexibility in accessing data. These addressing modes define the manner in which the CPU finds the data required to execute an instruction. The eight addressing modes are as follows:

- Inherent
- Immediate
- Direct
- Extended
- Indexed, no offset
- Indexed, 8-bit offset
- Indexed, 16-bit offset
- Relative

#### 12.1.1 Inherent

Inherent instructions are those that have no operand, such as return from interrupt (RTI) and stop (STOP). Some of the inherent instructions act on data in the CPU registers, such as set carry flag (SEC) and increment accumulator (INCA). Inherent instructions require no memory address and are 1 byte long. Table 12-1 lists the instructions that use inherent addressing.

**Table 12-1. Inherent Addressing Instructions**

<b>Instruction</b>	<b>Mnemonic</b>
Arithmetic Shift Left	ASLA, ASLX
Arithmetic Shift Right	ASRA, ASRX
Clear Carry Bit	CLC
Clear Interrupt Mask	CLI
Clear	CLRA, CLRX
Complement	COMA, COMX
Decrement	DECA, DECX
Increment	INCA, INCX
Logical Shift Left	LSLA, LSLX
Logical Shift Right	LSRA, LSRX
Multiply Index Register by Accumulator (Unsigned)	MUL
Negate	NEGA, NEGX
No Operation	NOP
Rotate Left through Carry	ROLA, ROLX
Rotate Right through Carry	RORA, RORX
Reset Stack Pointer	RSP
Return from Interrupt	RTI
Return from Subroutine	RTS
Set Carry Bit	SEC
Set Interrupt Mask	SEI
Enable $\overline{\text{IRQ}}$ and Stop Oscillator	STOP
Software Interrupt	SWI
Transfer Accumulator to Index Register	TAX
Test for Negative or Zero	TSTA, TSTX
Transfer Index Register to Accumulator	TXA
Enable Interrupts and Halt CPU	WAIT

### 12.1.2 Immediate

Immediate instructions are those that contain a value to be used in an operation with the value in the accumulator or index register. Immediate instructions require no memory address and are 2 bytes long. The opcode is the first byte and the immediate data value is the second byte. Table 12-2 lists the instructions that use immediate addressing.

**Table 12-2. Immediate Addressing Instructions**

Instruction	Mnemonic
Add Memory and Carry to Accumulator	ADC
Add Memory to Accumulator	ADD
Logical AND Memory with Accumulator	AND
Bit Test Memory with Accumulator (Logical Compare)	BIT
Arithmetic Compare Accumulator with Memory	CMP
Arithmetic Compare Index Register with Memory	CPX
Exclusive OR Memory with Accumulator	EOR
Load Accumulator from Memory	LDA
Load Index Register from Memory	LDX
Logical Inclusive OR Memory with Accumulator	ORA
Subtract Memory and Carry from Accumulator	SBC
Subtract Memory from Accumulator	SUB

### 12.1.3 Direct

Direct instructions can access any of the first 256 memory addresses with only 2 bytes. The first byte is the opcode, and the second is the low byte of the operand address. In direct addressing, the CPU automatically uses \$00 as the high byte of the operand address. BRSET and BRCLR are 3-byte instructions that use direct addressing to access the operand and relative addressing to specify a branch destination. Table 12-3 lists the instructions that use direct addressing.

**Table 12-3. Direct Addressing Instructions**

<b>Instruction</b>	<b>Mnemonic</b>
Add Memory and Carry to Accumulator	ADC
Add Memory to Accumulator	ADD
Logical AND Memory with Accumulator	AND
Arithmetic Shift Left	ASL
Arithmetic Shift Right	ASR
Clear Bit	BCLR
Bit Test Memory with Accumulator (Logical Compare)	BIT
Branch if Bit Clear	BRCLR
Branch if Bit Set	BRSET
Set Bit	BSET
Clear	CLR
Arithmetic Compare Accumulator with Memory	CMP
Complement	COM
Arithmetic Compare Index Register with Memory	CPX
Decrement	DEC
Exclusive OR Memory with Accumulator	EOR
Increment	INC
Jump	JMP
Jump to Subroutine	JSR
Load Accumulator from Memory	LDA
Load Index Register from Memory	LDX
Logical Shift Left	LSL
Logical Shift Right	LSR
Negate	NEG
Logical Inclusive OR Memory with Accumulator	ORA
Rotate Left through Carry	ROL
Rotate Right through Carry	ROR
Subtract Memory and Carry from Accumulator	SBC
Store Accumulator in Memory	STA
Store Index Register in Memory	STX
Subtract Memory from Accumulator	SUB
Test for Negative or Zero	TST

**12.1.4 Extended**

Extended instructions can access any address in memory with only 3 bytes. The first byte is the opcode; the second and third bytes are the high and low bytes of the operand address.

When using the Motorola assembler, the programmer does not need to specify whether an instruction is direct or extended. The assembler automatically selects the shortest form of the instruction. Table 12-4 lists the instructions that use the extended addressing mode.

**Table 12-4. Extended Addressing Instructions**

<b>Instruction</b>	<b>Mnemonic</b>
Add Memory and Carry to Accumulator	ADC
Add Memory to Accumulator	ADD
Logical AND Memory with Accumulator	AND
Bit Test Memory with Accumulator (Logical Compare)	BIT
Arithmetic Compare Accumulator with Memory	CMP
Arithmetic Compare Index Register with Memory	CPX
Exclusive OR Memory with Accumulator	EOR
Jump	JMP
Jump to Subroutine	JSR
Load Accumulator from Memory	LDA
Load Index Register from Memory	LDX
Logical Inclusive OR Memory with Accumulator	ORA
Subtract Memory and Carry from Accumulator	SBC
Store Accumulator in Memory	STA
Store Index Register in Memory	STX
Subtract Memory from Accumulator	SUB

### 12.1.5 Indexed, No Offset

Indexed instructions with no offset are 1-byte instructions that can access data with variable addresses within the first 256 memory locations. The index register contains the low byte of the conditional address of the operand. The CPU automatically uses \$00 as the high byte, so these instructions can address locations \$0000–\$00FF.

Indexed, no offset instructions are often used to move a pointer through a table or to hold the address of a frequently used RAM or I/O location. Table 12-5 lists the instructions that use indexed, no offset addressing.

### 12.1.6 Indexed, 8-Bit Offset

Indexed, 8-bit offset instructions are 2-byte instructions that can access data with variable addresses within the first 511 memory locations. The CPU adds the unsigned byte in the index register to the unsigned byte following the opcode. The sum is the conditional address of the operand. These instructions can access locations \$0000–\$01FE.

Indexed, 8-bit offset instructions are useful for selecting the kth element in an n-element table. The table can begin anywhere within the first 256 memory locations and could extend as far as location 510 (\$01FE). The k value would typically be in the index register, and the address of the beginning of the table would be in the byte following the opcode. Table 12-5 lists the instructions that use indexed, 8-bit offset addressing.

### 12.1.7 Indexed, 16-Bit Offset

Indexed, 16-bit offset instructions are 3-byte instructions that can access data with variable addresses at any location in memory. The CPU adds the unsigned byte in the index register to the 2 unsigned bytes following the opcode. The sum is the conditional address of the operand. The first byte after the opcode is the high byte of the 16-bit offset; the second byte is the low byte of the offset. These instructions can address any location in memory.

Indexed, 16-bit offset instructions are useful for selecting the kth element in an n-element table anywhere in memory.

As with direct and extended addressing, the Motorola assembler determines the shortest form of indexed addressing. Table 12-5 lists the instructions that use indexed, 16-bit offset addressing.

**Table 12-5. Indexed Addressing Instructions**

Instruction	Mnemonic	No Offset	8-Bit Offset	16-Bit Offset
Add Memory and Carry to Accumulator	ADC	√	√	√
Add Memory to Accumulator	ADD	√	√	√
Logical AND Memory with Accumulator	AND	√	√	√
Arithmetic Shift Left	ASL	√	√

Subtract Memory from Accumulator	SUB	√	√	√
Test for Negative or Zero	TST	√	√	

Freescale Semiconductor, Inc.

**12.1.8 Relative**

Relative addressing is only for branch instructions and bit test and branch instructions. If the branch condition is true, the CPU finds the conditional branch destination by adding the signed byte following the opcode to the contents of the program counter. If the branch condition is not true, the CPU goes to the next instruction. The offset is a signed, two's complement byte that gives a branching range of  $-127$  to  $+128$  bytes from the address of the next location after the branch instruction.

When using the Motorola assembler, the programmer does not need to calculate the offset, because the assembler determines the proper offset and verifies that it is within the span of the branch. Table 12-6 lists the instructions that use relative addressing.

**Table 12-6. Relative Addressing Instructions**

Instruction	Mnemonic
Branch if Carry Clear	BCC
Branch if Carry Set	BCS
Branch if Equal	BEQ
Branch if Half-Carry Clear	BHCC
Branch if Half-Carry Set	BHCS
Branch if Higher	BHI
Branch if Higher or Same	BHS
Branch if Interrupt Line High	BIH
Branch if Interrupt Line Low	BIL
Branch if Lower	BLO
Branch if Lower or Same	BLS
Branch if Interrupt Mask Clear	BMC
Branch if Minus	BMI
Branch if Interrupt Mask Set	BMS
Branch if Not Equal	BNE
Branch if Plus	BPL
Branch Always	BRA
Branch if Bit Clear	BRCLR
Branch if Bit Set	BRSET
Branch Never	BRN
Branch to Subroutine	BSR

## 12.2 Instruction Set

The MCU instructions fall into the following five categories:

- Register/memory
- Read-modify-write
- Jump/branch
- Bit manipulation
- Control

### 12.2.1 Register/Memory Instructions

Most of these instructions use two operands. One operand is in either the accumulator or the index register. The CPU finds the other operand in memory. Most register/memory instructions use the following addressing modes:

- Immediate
- Direct
- Extended
- Indexed, no offset
- Indexed, 8-bit offset
- Indexed, 16-bit offset

Table 12-7 lists the register/memory instructions.

**Table 12-7. Register/Memory Instructions**

Instruction	Mnemonic
Load Accumulator from Memory	LDA
Load Index Register from Memory	LDX
Store Accumulator in Memory	STA
Store Index Register in Memory	STX
Add Memory to Accumulator	ADD
Add Memory and Carry to Accumulator	ADC
Subtract Memory from Accumulator	SUB
Subtract Memory and Carry from Accumulator	SBC
Logical AND Memory with Accumulator	AND
Logical Inclusive OR Memory with Accumulator	ORA
Arithmetic Compare Accumulator with Memory	CMP
Arithmetic Compare Index Register with Memory	CPX
Bit Test Memory with Accumulator (Logical Compare)	BIT
Multiply Index Register by Accumulator (Unsigned)	MUL

### 12.2.2 Read-Modify-Write Instructions

These instructions read a memory location or a register, modify its contents, and write the modified value back to the memory location or to the register. The test for negative or zero (TST) instruction is an exception to the read-modify-write sequence because it does not write a replacement value. Read-modify-write instructions use the following addressing modes:

- Inherent
- Direct
- Indexed, no offset
- Indexed, 8-bit offset

Table 11-8 lists the read-modify-write instructions.

**Table 12-8. Read-Modify-Write Instructions**

Instruction	Mnemonic
Increment	INC
Decrement	DEC
Clear	CLR
Complement	COM
Negate (Two's Complement)	NEG
Rotate Left through Carry	ROL
Rotate Right through Carry	ROR
Logical Shift Left	LSL
Logical Shift Right	LSR
Arithmetic Shift Right	ASR
Test for Negative or Zero	TST

### 12.2.3 Jump/Branch Instructions

Jump instructions allow the CPU to interrupt the normal sequence of the program counter. The unconditional jump (JMP) and jump to subroutine (JSR) instructions have no register operand. Jump instructions use the following addressing modes:

- Direct
- Extended
- Indexed, no offset
- Indexed, 8-bit offset
- Indexed, 16-bit offset

Branch instructions allow the CPU to interrupt the normal sequence of the program counter when a test condition is met. If the test condition is not met, the branch instruction is not performed. All branch instructions use relative addressing.

Bit test and branch instructions cause a branch based on the state of any readable bit in the first 256 memory locations. These 3-byte instructions use a combination of direct addressing and relative addressing. The direct address of the byte to be tested is in the byte following the opcode. The third byte is the signed offset byte. The CPU finds the conditional branch destination by adding the third byte to the program counter if the specified bit tests true. The bit to be tested and its condition (set or clear) are part of the opcode. The span of branching is from -128 to +127 from the address of the next location after the branch instruction. The CPU also transfers the tested bit to the carry/borrow bit of the condition code register. Table 12-9 lists the jump and branch instructions.

**Table 12-9. Jump and Branch Instructions**

Instruction	Mnemonic
Branch Always	BRA
Branch Never	BRN
Branch if Bit Clear	BRCLR
Branch if Bit Set	BRSET
Branch if Higher	BHI
Branch if Lower or Same	BLS
Branch if Carry Clear	BCC
Branch if Higher or Same	BHS
Branch if Carry Set	BCS
Branch if Lower	BLO
Branch if Not Equal	BND
Branch if Equal	BEQ
Branch if Half-Carry Bit Clear	BHCC
Branch if Half-Carry Bit Set	BHCS
Branch if Plus	BPL
Branch if Minus	BMI
Branch if Interrupt Mask Clear	BMC
Branch if Interrupt Mask Set	BMS
Branch if Interrupt Line Low	BIL
Branch if Interrupt Line High	BIH
Branch to Subroutine	BSR
Jump	JMP
Jump to Subroutine	JSR

### 12.2.4 Bit Manipulation Instructions

The CPU can set or clear any writable bit in the first 256 bytes of memory. Port registers, port data direction registers, timer registers, and on-chip RAM locations are in the first 256 bytes of memory. The CPU can also test and branch based on the state of any bit in any of the first 256 memory locations. Bit manipulation instructions use direct addressing. Table 12-10 lists these instructions.

**Table 12-10. Bit Manipulation Instructions**

Instruction	Mnemonic
Set Bit	BSET
Clear Bit	BCLR
Branch if Bit Clear	BRCLR
Branch if Bit Set	BRSET

### 12.2.5 Control Instructions

These register reference instructions control CPU operation during program execution. Control instructions, listed in Table 12-11, use inherent addressing.

**Table 12-11. Control Instructions**

Instruction	Mnemonic
Transfer Accumulator to Index Register	TAX
Transfer Index Register to Accumulator	TXA
Set Carry Bit	SEC
Clear Carry Bit	CLC
Set Interrupt Mask	SEI
Clear Interrupt Mask	CLI
Software Interrupt	SWI
Return from Subroutine	RTI
Reset Stack Pointer	RSP
No Operation	NOP
Stop	STOP
Wait	WAIT

### 12.2.6 Instruction Set Summary and Opcode Map

Table 12-12 shows all MC68HC05C12 instructions in all possible addressing modes.

Table 12-13 is an opcode map of the M68HC05 instruction set.

For each instruction, the operand construction and the execution time in internal clock cycles ( $t_{CYC}$ ) are shown. One internal clock cycle equals two oscillator input cycles. The following legend summarizes the symbols and abbreviations used in Table 12-12.

#### Abbreviations and Symbols

A	Accumulator	PCH	Program counter high byte
C	Carry/borrow flag	PCL	Program counter low byte
CCR	Condition code register	REL	Relative addressing mode
dd	Direct address of operand	<i>rel</i>	Offset byte in relative addressing
dd rr	Direct address (dd) of operand and relative offset (rr) of branch instruction	rr	Offset byte of branch instruction
DIR	Direct addressing mode	SP	Stack pointer
ee ff	High (ee) and low (ff) bytes of offset in indexed, 16-bit offset addressing	X	Index register
EXT	Extended addressing mode	Z	Zero flag
ff	Offset byte in indexed, 8-bit offset addressing	#	Immediate value
H	Half-carry flag	•	AND
hh ll	High (hh) and low (ll) bytes of operand address in extended addressing	–	Not affected
I	Interrupt mask	?	If
ii	Operand byte in immediate addressing	—	NOT
IMM	Immediate addressing mode	( )	Contents of
INH	Inherent addressing mode	←	Is loaded with
IX	Indexed, no offset addressing mode	:	Concatenated with
IX1	Indexed, 8-bit offset addressing mode	×	Multiplication
IX2	Indexed, 16-bit offset addressing mode	–( )	Negation (two's complement)
M	Any memory location (1 byte)	+	Inclusive OR
N	Negative flag	↕	Set if true; clear if not true
<i>n</i>	Any bit (7,6,5 . . . 0)	⊕	Exclusive OR
<i>opr</i>	Operand	+	Addition
PC	Program counter	–	Subtraction

## SECTION 13 ELECTRICAL SPECIFICATIONS

This section contains electrical and timing specifications.

### 13.1 Maximum Ratings

Maximum ratings are the extreme limits the device can be exposed to without causing permanent damage to the chip. The MCU contains circuitry that protects the inputs against damage from high static voltages; however, do not apply voltages higher than those shown in Table 13-1. Keep  $V_{IN}$  and  $V_{OUT}$  within the range  $V_{SS} \leq (V_{IN} \text{ or } V_{OUT}) \leq V_{DD}$ . Connect unused inputs to appropriate logical voltage level, either  $V_{SS}$  or  $V_{DD}$ .

**Table 13-1. Maximum Ratings**

Rating	Symbol	Value	Unit
Supply Voltage	$V_{DD}$	-0.3 to +7.0	V
Current Drain Per Pin (Excluding $V_{DD}$ and $V_{SS}$ )	I	25	mA
$\overline{IRQ}$ Pin Only		$V_{SS} - 0.3$ to $2 \times V_{DD} + 0.3$	V
Storage Temperature Range	$T_{STG}$	-65 to +150	°C

### 13.2 Operating Temperature Range

**Table 13-2. Operating Temperature Range**

Rating	Symbol	Value	Unit
Operating Temperature Range MC68HC05C12P, FN MC68HC05C12CP, CFN, CB, CFB MC68HC05C12B, FB	$T_A$	$T_L$ to $T_H$ 0 to +70 -40 to +85 0 to +70	$^{\circ}\text{C}$

**NOTES:**

- |  |   |
|--|---|
| 1. P = Plastic dual-in-line package (PDIP)                 | 4. B = Shrink dual-in-line package (SDIP) |
| 2. FN = Plastic-leaded chip carrier (PLCC)                 | 5. FB = Quad flat pack (QFP)              |
| 3. C = Extended temperature range (-40 to +85 $^{\circ}$ ) |   |

### 13.3 Thermal Characteristics

**Table 13-3. Thermal Characteristics**

Characteristic	Symbol	Value	Unit
Thermal Resistance	$\theta_{JA}$		$^{\circ}\text{C}/\text{W}$
Plastic Dual-In-Line Package (PDIP)		60	
Plastic Leaded Chip Carrier (PLCC)		70	
Quad Flat Pack (QFP)		95	
Plastic Shrink DIP (SDIP)		60	

### 13.4 Power Considerations

The average chip-junction temperature,  $T_J$ , in °C, can be obtained from:

$$T_J = T_A + (P_D \times \theta_{JA}) \tag{1}$$

where:

$T_A$  = Ambient temperature, °C

$\theta_{JA}$  = Package thermal resistance, junction to ambient, °C/W

$P_D = P_{INT} + P_{I/O}$

$P_{INT} = I_{DD} \times V_{DD}$  watts (chip internal power)

$P_{I/O}$  = Power dissipation on input and output pins (user-determined)

For most applications  $P_{I/O} \ll P_{INT}$  and can be neglected.

Following is an approximate relationship between  $P_D$  and  $T_J$  (neglecting  $P_{I/O}$ ):

$$P_D = K \div (T_J + 273 \text{ }^\circ\text{C}) \tag{2}$$

Solving equations (1) and (2) for K gives:

$$K = P_D \times (T_A + 273 \text{ }^\circ\text{C}) + \theta_{JA} \times (P_D)^2 \tag{3}$$

where K is a constant pertaining to the particular part. K can be determined from equation (3) by measuring  $P_D$  (at equilibrium) for a known  $T_A$ . Using this value of K, the values of  $P_D$  and  $T_J$  can be obtained by solving equations (1) and (2) iteratively for any value of  $T_A$ .

Interrupt Pulse Period	$t_{LIL}$	( <sup>4</sup> )	—	$t_{CYC}$
OSC1 Pulse Width	$t_{OH}, t_{OL}$	200	—	ns

- $V_{DD} = 3.3 \text{ Vdc} \pm 0.3 \text{ Vdc}$ ,  $V_{SS} = 0 \text{ Vdc}$ ,  $T_A = -40^\circ$  to  $+85^\circ \text{ C}$ , unless otherwise noted.
- Because a 2-bit prescaler in the timer must count four internal cycles ( $t_{CYC}$ ), this is the limiting minimum factor in determining the timer resolution.
- The minimum period  $t_{LTL}$  should not be less than the number of cycle times it takes to execute the capture interrupt service routine plus 24  $t_{CYC}$ .
- The minimum  $t_{LIL}$  should not be less than the number of cycle times it takes to execute the interrupt service routine plus 21  $t_{CYC}$ .

\*Refer to timer resolution data in tables 13-6 and 13-7.

Figure 13-4. TCAP Timing Relationships

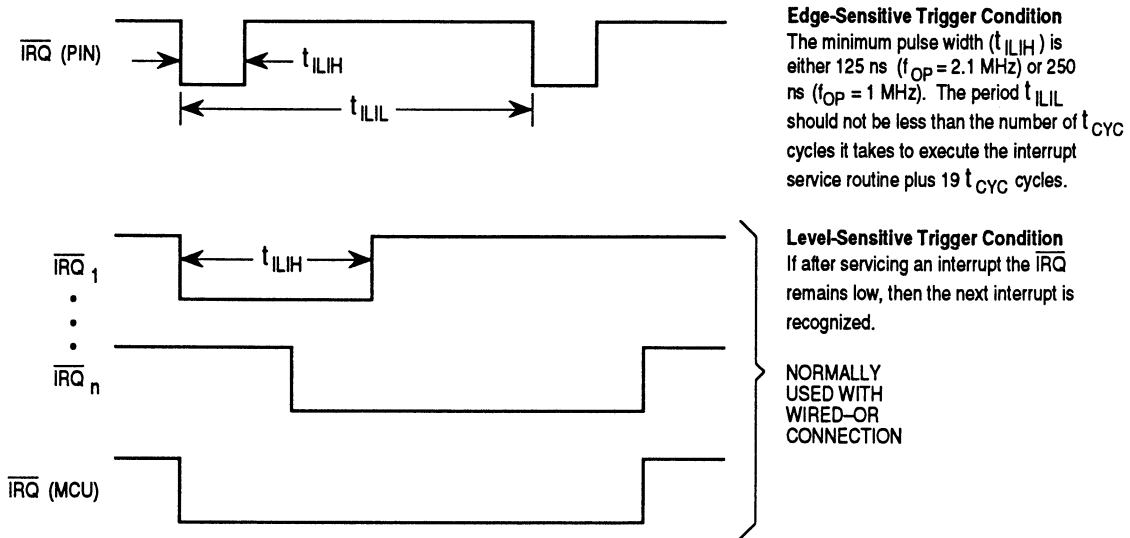

Figure 13-5. External Interrupt Timing

NOTES:

1. Power-on reset threshold is typically between 1 V and 2 V.
2. OSC1 line is meant to represent time only, not frequency.
3. Internal clock, internal address bus, and internal data bus signals are not available externally.

**Figure 13-7. Power-on Reset Timing**

NOTES:

1. Internal clock, internal address bus, and internal data bus signals are not available externally.
2. Next rising edge of internal clock after rising edge of RESET initiates reset sequence.

**Figure 13-8. External Reset Timing**

## SECTION 14 MECHANICAL SPECIFICATIONS

This section describes the dimensions of the following packages: plastic dual-in-line (PDIP), plastic-leaded chip carrier (PLCC), quad flat pack (QFP), and plastic shrink DIP (SDIP).

### 14.1 Plastic Dual-in-Line Package (PDIP)

**NOTES:**

1. POSITIONAL TOLERANCE OF LEADS (D), SHALL BE WITHIN 0.25 mm (0.010) AT MAXIMUM MATERIAL CONDITION, IN RELATION TO SEATING PLANE AND EACH OTHER.
2. DIMENSION L TO CENTER OF LEADS WHEN FORMED PARALLEL.
3. DIMENSION B DOES NOT INCLUDE MOLD FLASH.

DIM	MILLIMETERS		INCHES	
	MIN	MAX	MIN	MAX
A	51.69	52.45	2.035	2.065
B	13.72	14.22	0.540	0.560
C	3.94	5.08	0.155	0.200
D	0.36	0.56	0.014	0.022
F	1.02	1.52	0.040	0.060
G	2.54 BSC		0.100 BSC	
H	1.65	2.16	0.065	0.085
J	0.20	0.38	0.008	0.015
K	2.92	3.43	0.115	0.135
L	15.24 BSC		0.600 BSC	
M	0°	15°	0°	15°
N	0.51	1.02	0.020	0.040

Figure 14-1. MC68HC05C12P (Case # 711-03)

14.2 Plastic-Leaded Chip Carrier (PLCC)

- NOTES:
- DATUMS -L-, -M-, AND -N- ARE DETERMINED WHERE TOP OF LEAD SHOULDER EXITS PLASTIC BODY AT MOLD PARTING LINE.
  - DIMENSION G1, TRUE POSITION TO BE MEASURED AT DATUM -T-, SEATING PLANE.
  - DIMENSIONS R AND U DO NOT INCLUDE MOLD FLASH. ALLOWABLE MOLD FLASH IS (0.010) 0.25 PER SIDE.
  - DIMENSIONING AND TOLERANCING PER ANSI Y14.5M, 1982.
  - CONTROLLING DIMENSION: INCH.
  - THE PACKAGE TOP MAY BE SMALLER THAN THE PACKAGE BOTTOM BY UP TO 0.012 (0.300). DIMENSIONS R AND U ARE DETERMINED AT THE OUTERMOST EXTREMES OF THE PLASTIC BODY EXCLUSIVE OF MOLD FLASH, TIE BAR BURRS, GATE BURRS AND INTERLEAD FLASH, BUT INCLUDING ANY MISMATCH BETWEEN THE TOP AND BOTTOM OF THE PLASTIC BODY.
  - DIMENSION H DOES NOT INCLUDE DAMBAR PROTRUSION OR INTRUSION. THE DAMBAR PROTRUSION(S) SHALL NOT CAUSE THE H DIMENSION TO BE GREATER THAN 0.037 (0.940). THE DAMBAR INTRUSION(S) SHALL NOT CAUSE THE H DIMENSION TO BE SMALLER THAN 0.025 (0.635).

DIM	INCHES		MILLIMETERS	
	MIN	MAX	MIN	MAX
A	0.685	0.695	17.40	17.65

## SECTION 15 ORDERING INFORMATION

This section contains instructions for ordering custom-masked ROM MCUs.

### 15.1 MCU Ordering Forms

To initiate an order for a ROM-based MCU, first obtain the current ordering form for the MCU from a Motorola representative. Submit the following items when ordering MCUs:

- A current MCU ordering form that is **completely filled out** (Contact your Motorola sales office for assistance.)
- A copy of the customer specification if the customer specification deviates from the Motorola specification for the MCU
- Customer's application program on one of the media listed in **15.2 Application Program Media**

The current MCU ordering form is also available through the Motorola Freeware Bulletin Board Service (BBS). The telephone number is (512) 891-FREE. After making the connection, type `bbs` in lowercase letters and press the return key to start the BBS software.

## 15.2 Application Program Media

Please deliver the application program to Motorola in one of the following media:

- Macintosh®<sup>1</sup> 3-1/2-inch diskette (double-sided 800K or double-sided high-density 1.4M)
- MS-DOS®<sup>2</sup> or PC-DOS®<sup>3</sup> 3-1/2-inch diskette (double-sided 720K or double-sided high-density 1.44M)
- MS-DOS® or PC-DOS® 5-1/4-inch diskette (double-sided double-density 360K or double-sided high-density 1.2M)
- EPROM(s) 2716, 2732, 2764, 27128, 27256, or 27512 (depending on the size of the memory map of the MCU)

Use positive logic for data and addresses.

### 15.2.1 Diskettes

If submitting the application program on a diskette, clearly label the diskette with the following information:

- Customer name
- Customer part number
- Project or product name
- File name of object code
- Date
- Name of operating system that formatted diskette
- Formatted capacity of diskette

On diskettes, the application program must be in Motorola's S-record format (S1 and S9 records), a character-based object file format generated by M6805 cross assemblers and linkers.

---

<sup>1</sup> Macintosh is a registered trademark of Apple Computer, Inc.

<sup>2</sup> MS-DOS is a registered trademark of Microsoft, Inc.

<sup>3</sup> PC-DOS is a registered trademark of International Business Machines Corporation.

**NOTE**

Begin the application program at the first user ROM location. Program addresses must correspond exactly to the available on-chip user ROM addresses as shown in the memory map. **Write \$00 in all non-user ROM locations or leave all non-user ROM locations blank.** Refer to the current MCU ordering form for additional requirements.

If the memory map has two user ROM areas with the same addresses, write the two areas in separate files on the diskette. Label the diskette with both file names.

In addition to the object code, a file containing the source code can be included. Motorola keeps this code confidential and uses it only to expedite ROM pattern generation in case of any difficulty with the object code. Label the diskette with the file name of the source code.

**15.2.2 EPROMs**

If submitting the application program in an EPROM, clearly label the EPROM with the following information:

- Customer name
- Customer part number
- Checksum
- Project or product name
- Date

**NOTE**

Begin the application program at the first user ROM location. Program addresses must correspond exactly to the available on-chip user ROM addresses as shown in the memory map. **Write \$00 in all non-user ROM locations.** Refer to the current MCU ordering form for additional requirements.

Submit the application program in one EPROM large enough to contain the entire memory map. If the memory map has two user ROM areas with the same addresses, write the two areas on separate EPROMs. Label the EPROMs with the addresses they contain.

Pack EPROMs securely in a conductive IC carrier for shipment. Do not use Styrofoam.

### 15.3 ROM Program Verification

The primary use for the on-chip ROM is to contain the customer's application program. Customers develop and debug the application program and then submit the MCU order along with their application programs.

Motorola inputs the customer's application program code into a computer program that generates a listing verify file. The listing verify file represents the memory map of the MCU. The listing verify file contains the user ROM code and may also contain non-user ROM code, such as self-check code. Motorola sends the customer a computer printout of the listing verify file along with a listing verify form.

To aid the customer in checking the listing verify file, Motorola will program the listing verify file into customer-supplied blank EPROMs or preformatted Macintosh or DOS disks. All original pattern media is filed for contractual purposes and is not returned.

Check the listing verify file thoroughly, then complete and sign the listing verify form and return the listing verify form to Motorola. The signed listing verify form constitutes the contractual agreement for the creation of the custom mask.

### 15.4 ROM Verification Units (RVUs)

After receiving the signed listing verify form, Motorola manufactures a custom photographic mask. The mask contains the customer's application program and is used to process silicon wafers. The application program cannot be changed after the manufacture of the mask begins. Motorola then produces ten MCUs, called RVUs, and sends the RVUs to the customer. RVUs are usually packaged in unmarked ceramic and tested to 5 Vdc at room temperature. RVUs are not tested to environmental extremes because their sole purpose is to demonstrate that the customer's user ROM pattern was properly implemented. The ten RVUs are free of charge with the minimum order quantity but are not production parts. RVUs are not guaranteed by Motorola Quality Assurance.

### 15.5 MC Order Numbers

Table 15-1 lists the order numbers for all packages.

**Table 15-1. MC Order Numbers**

MC Order Number	Temperature
MC68HC05C12P, FN	-0° to 70 °C
MC68HCL05C12P, FN (Low Power)	-0° to 70 °C
MC68HSC05C12P, FN (High Speed)	-0° to 70 °C
MC68HC05C12CP, CFN, CB, CFB	-40° to 70 °C
MC68HSC05C12CP, CFN, CB, CFB (High Speed)	-40° to 70 °C
MC68HC05C12B, FB	-0° to 70 °C
MC68HCL05C12B, FB (Low Power)	-0° to 70 °C
MC68HSC05C12B, FB (High Speed)	-0° to 70 °C

**NOTES:**

- |   |   |
|---|---|
| 1. P = Plastic dual-in-line package (PDIP)      | 4. B = Shrink dual-in-line package (SDIP) |
| 2. FN = Plastic-leaded chip carrier (PLCC)      | 5. FB = Quad flat pack (QFP)              |
| 3. C = Extended temperature range (-40 to +85°) |   |

**APPENDIX A  
MC68HCL05C12**

Appendix A introduces the MC68HCL05C12, a low power version of the MC68HC05C12. The technical data applying to the MC68HC05C12 applies to the MC68HCL05C12 with the exceptions given in this appendix.

**A.1 DC Electrical Characteristics**

The data in Table A-1 replaces the corresponding data in **Table 13.2. Operating Temperature Range.**

**Table A-1. Low Power Operating Temperature Range**

Rating	Symbol	Value	Unit
Operating Temperature Range MC68HCL05C12P, FN, B, FB	$T_A$	TL to TH 0 to +70	°C

NOTES:

- |  |   |
|--|---|
| 1. P = Plastic dual-in-line package (PDIP) | 3. B = Shrink dual-in-line package (SDIP) |
| 2. FN = Plastic-leaded chip carrier (PLCC) | 4. FB = Quad flat pack (QFP)              |

The data in tables 13-4 and 13-5 (MC68HC05C12 DC electrical characteristics data) apply to the MC68HCL05C12 with the exceptions given in tables A-2, A-3, and A-4.

**Table A-2. Low Power Output Voltage ( $V_{DD} = 1.8\text{--}2.4\text{ Vdc}$ )**

( $I_{LOAD} = 5\text{ mA}$ ) PC7	$V_{OL}$	—	—	0.3	

**Table A-4. Low Power Supply Current**

Characteristic <sup>(1)</sup>	Symbol	Min	Typ	Max	Unit
Supply Current (4.5–5.5 Vdc @ $f_{BUS} = 2.1$ MHz Run Wait Stop 25 °C 0° to +70 °C (Standard)	$I_{DD}$	—	3.50	4.25	mA
		—	1.6	2.25	mA
		—	1	15	μA
		—	—	25	μA
Supply Current (2.4–3.6 Vdc @ $f_{BUS} = 1.0$ MHz Run <sup>(2)</sup> Wait <sup>(3)</sup> Stop <sup>(4)</sup> 25 °C 0° to +70 °C (Standard)	$I_{DD}$	—	1.00	1.4	mA
		—	0.7	1.0	mA
		—	1	5	μA
		—	—	10	μA
Supply Current (2.5–3.6 Vdc @ $f_{BUS} = 500$ kHz Run Wait Stop 25 °C 0° to +70 °C (Standard)	$I_{DD}$	—	500	750	μA
		—	300	500	μA
		—	1	5	μA
		—	—	10	μA
Supply Current (1.8–2.4 Vdc @ $f_{BUS} = 500$ kHz Run Wait Stop 25 °C 0° to +70 °C (Standard)	$I_{DD}$	—	300	600	μA
		—	250	400	μA
		—	1	2	μA
		—	—	5	μA

**NOTES:**

1. Typical values reflect measurements taken on average processed devices at the midpoint of voltage range, 25 °C only.
2. Run (operating)  $I_{DD}$  measured using external square wave clock source ( $f_{OSC} = 2.1$  MHz); all other inputs 0.2 V from rail. No dc loads. Less than 50 pF on all outputs.  $C_L = 20$  pF on OSC2.
3. Wait  $I_{DD}$ : all ports configured as inputs;  $V_{IL} = 0.2$  V,  $V_{IH} = V_{DD} - 0.2$  V. OSC2 capacitance linearly affects Wait  $I_{DD}$ .
4. Stop  $I_{DD}$ : all ports configured as inputs;  $V_{IL} = 0.2$  V,  $V_{IH} = V_{DD} - 0.2$  V. Stop  $I_{DD}$  is measured with OSC1 =  $V_{SS}$ .

**APPENDIX B  
MC68HSC05C12**

Appendix B introduces the MC68HSC05C12, a high-speed version of the MC68HC05C12. The technical data applying to the MC68HC05C12 applies to the MC68HSC05C12 with the exceptions given in this appendix.

**B.1 DC Electrical Characteristics**

The data in Table B-1 replaces the corresponding data in **Table 13.2 Operating Temperature Range**.

**Table B-1. High-Speed Operating Temperature Range**

Rating	Symbol	Value	Unit
Operating Temperature Range MC68HSC05C12P, FN MC68HSC05C12CP, CFN, CB, CFB MC68HSC05C12B, FB	$T_A$	$T_L$ to $T_H$ 0 to +70 -40 to +85 0 to +70	°C

NOTES:

- 1. P = Plastic dual-in-line package (PDIP)
- 2. FN = Plastic-leaded chip carrier (PLCC)
- 3. C = Extended temperature range (-40 to +85°)
- 4. B = Shrink dual-in-line package (SDIP)
- 5. FB = Quad flat pack (QFP)

The data in tables 13-4 and 13-5 (MC68HC05C12 DC electrical characteristics data) apply to the MC68HSC05C12 with the exceptions given in Table B-2.

**Table B-2. High-Speed Supply Current**

Characteristic <sup>(1)</sup>	Symbol	Min	Typ	Max	Unit
Supply Current (4.5–5.5 Vdc @ f <sub>BUS</sub> = 4.0 MHz)	I <sub>DD</sub>	—	7.00	11.0	mA
Run <sup>(2)</sup>		—	2.00	6.50	mA
Wait <sup>(3)</sup>		—	1	20	μA
Stop <sup>(4)</sup>		—	—	40	μA
25 °C		—	—	50	μA
0° to +70 °C (Standard)		—	—	—	—
Supply Current (2.4–3.6 Vdc @ f <sub>BUS</sub> = 2.0 MHz)	I <sub>DD</sub>	—	2.50	4.00	mA
Run <sup>(2)</sup>		—	1.00	2.00	mA
Wait <sup>(3)</sup>		—	1	8	μA
Stop <sup>(4)</sup>		—	—	16	μA
25 °C		—	—	20	μA
0° to +70 °C (Standard)		—	—	—	—
–40° to 85 °C (Standard)	—	—	—	—	

**NOTES:**

1. Typical values reflect measurements taken on average processed devices at the midpoint of voltage range, 25 °C only.
2. Run (operating) I<sub>DD</sub> measured using external square wave clock source (f<sub>OSC</sub> = 8.0 MHz); all other inputs 0.2 V from rail. No dc loads. Less than 50 pF on all outputs. C<sub>L</sub> = 20 pF on OSC2.
3. Wait I<sub>DD</sub> measured using external square wave clock source (f<sub>OSC</sub> = 8.0 MHz); all ports configured as inputs; V<sub>IL</sub> = 0.2 V, V<sub>IH</sub> = V<sub>DD</sub>–0.2 V. OSC2 capacitance linearly affects Wait I<sub>DD</sub>.
4. Stop I<sub>DD</sub>: all ports configured as inputs; V<sub>IL</sub> = 0.2 V, V<sub>IH</sub> = V<sub>DD</sub>–0.2 V. Stop I<sub>DD</sub> measured with OSC1 = V<sub>SS</sub>.

**B.2 Control Timing (V<sub>DD</sub> = 4.5–5.5 Vdc)**

The data in tables 13-6, 13-7, 13-8, and 13-9 (MC68HC05C12 control timing data) apply to the MC68HSC05C12 with the exceptions given in tables B-3, B-4, B-5, and B-6.

**Table B-3. High-Speed Control Timing ( $V_{DD} = 4.5\text{--}5.5\text{ Vdc}$ )**

$\overline{RESET}$ Pulse Width	$t_{RL}$	1.5	—	$t_{CYC}$
Timer Resolution <sup>(1)</sup> Input Capture Pulse Width Input Capture Pulse Width	$t_{RESL}$ $t_{TH}$ or $t_{TL}$ $t_{HTL}$	4.0 63 (2)	— — —	$t_{CYC}$ ns $t_{CYC}$
Interrupt Pulse Width Low (Edge-Triggered)	$t_{ILIH}$	63	—	ns
Interrupt Pulse Period	$t_{ILIL}$	(3)	—	$t_{CYC}$
OSC1 Pulse Width	$t_{OH}$ or $t_{OL}$	45	—	ns

1. Because a 2-bit prescaler in the timer must count four internal cycles ( $t_{CYC}$ ), this is the limiting minimum factor in determining the timer resolution.
2. The minimum period  $t_{TLTL}$  should not be less than the number of cycle times it takes to execute the capture interrupt service routine plus 24  $t_{CYC}$ .
3. The minimum  $t_{ILIL}$  should not be less than the number of cycle times it takes to execute the interrupt service routine plus 21  $t_{CYC}$ .

**Table B-4. High-Speed Control Timing ( $V_{DD} = 2.4\text{--}3.6\text{ Vdc}$ )**

Characteristic	Symbol	Min	Max	Unit
Oscillator Frequency Crystal Oscillator Option External Clock Operation	$f_{OSC}$	— dc	4.0 4.0	MHz
Internal Operating Frequency ( $f_{OSC} + 2$ ) Crystal Option External Clock Operation	$f_{OP}$	— dc	2.0 2.0	MHz
Cycle Time	$t_{CYC}$	500	—	ns
Crystal Oscillator Startup Time	$t_{OXOV}$		100	ms
Stop Recovery Startup Time	$t_{ILCH}$		100	ms
$\overline{RESET}$ Pulse Width	$t_{RL}$	1.5	—	$t_{CYC}$
Timer Resolution <sup>(1)</sup> Input Capture Pulse Width Input Capture Pulse Width	$t_{RESL}$ $t_{TH}$ or $t_{TL}$ $t_{HTL}$	4.0 126 (2)	— — —	$t_{CYC}$ ns $t_{CYC}$
Interrupt Pulse Width Low (Edge-Triggered)	$t_{ILIH}$	126	—	ns
Interrupt Pulse Period	$t_{ILIL}$	(3)	—	$t_{CYC}$
OSC1 Pulse Width	$t_{OH}$ or $t_{OL}$	90	—	ns

1. Because a 2-bit prescaler in the timer must count four internal cycles ( $t_{CYC}$ ), this is the limiting minimum factor in determining the timer resolution.
2. The minimum period  $t_{TLTL}$  should not be less than the number of cycle times it takes to execute the capture interrupt service routine plus 24  $t_{CYC}$ .
3. The minimum  $t_{ILIL}$  should not be less than the number of cycle times it takes to execute the interrupt service routine plus 21  $t_{CYC}$ .

**Table B-5. High-Speed SPI Timing ( $V_{DD} = 4.5\text{--}5.5\text{ Vdc}$ )**

Num	Characteristic	Symbol	Min	Max	Unit
	Operating Frequency Master Slave	$f_{OP(M)}$ $f_{OP(S)}$	dc dc	0.5 4.0	$f_{OP}$ MHz
1	Cycle Time Master Slave	$t_{CYC(M)}$ $t_{CYC(S)}$	2.0 250	— —	$t_{CYC}$ ns
2	Enable Lead Time Master Slave	$t_{LEAD(M)}$ $t_{LEAD(S)}$	† 125	— —	ns ns
3	Enable Lag Time Master Slave	$t_{LAG(M)}$ $t_{LAG(S)}$	† 375	— —	ns ns
4	Clock (SCK) High Time Master Slave	$t_{W(SCKH)M}$ $t_{W(SCKH)S}$	170 95	— —	ns ns
5	Clock (SCK) Low Time Master Slave	$t_{W(SCKL)M}$ $t_{W(SCKL)S}$	170 95	— —	ns ns
6	Data Setup Time (Inputs) Master Slave	$t_{SU(M)}$ $t_{SU(S)}$	50 50	— —	ns ns
7	Data Hold Time (Inputs) Master Slave	$t_{H(M)}$ $t_{H(S)}$	50 50	— —	ns ns
8	Slave Access Time (Time to Data Active from High-Impedance State)	$t_A$	0	60	ns
9	Slave Disable Time (Hold Time to High-Impedance State)	$t_{DIS}$	—	120	ns
10	Data Valid Master (Before Capture Edge) Slave (After Enable Edge)‡	$t_{V(M)}$ $t_{V(S)}$	0.25 —	— 120	$t_{CYC(M)}$ ns
11	Data Hold Time (Outputs) Master (After Capture Edge) Slave (After Enable Edge)	$t_{HO(M)}$ $t_{HO(S)}$	0.25 0	— —	$t_{CYC(M)}$ ns
12	Rise Time (20% $V_{DD}$ to 70% $V_{DD}$ , $C_L = 200\text{ pF}$ ) SPI Outputs (SCK, MOSI, and MISO) SPI Inputs (SCK, MOSI, MISO, and SS)	$t_{RM}$ $t_{RS}$	— —	50 1.0	ns $\mu\text{s}$
13	Fall Time (70% $V_{DD}$ to 20% $V_{DD}$ , $C_L = 200\text{ pF}$ ) SPI Outputs (SCK, MOSI, and MISO) SPI Inputs (SCK, MOSI, MISO, and SS)	$t_{FM}$ $t_{FS}$	— —	50 1.0	ns $\mu\text{s}$

† Signal production depends on software.

‡ Assumes 200 pF load on all SPI pins.

**Table B-6. High-Speed SPI Timing ( $V_{DD} = 2.4\text{--}3.6\text{ Vdc}$ )**

Num	Characteristic	Symbol	Min	Max	Unit
	Operating Frequency Master Slave	$f_{OP(M)}$ $f_{OP(S)}$	dc dc	0.5 2.0	$f_{OP}$ MHz
1	Cycle Time Master Slave	$t_{CYC(M)}$ $t_{CYC(S)}$	2.0 500	— —	$t_{CYC}$ ns
2	Enable Lead Time Master Slave	$t_{LEAD(M)}$ $t_{LEAD(S)}$	† 250	— —	ns ns
3	Enable Lag Time Master Slave	$t_{LAG(M)}$ $t_{LAG(S)}$	† 750	— —	ns ns
4	Clock (SCK) High Time Master Slave	$t_{W(SCKH)M}$ $t_{W(SCKH)S}$	360 200	— —	ns ns
5	Clock (SCK) Low Time Master Slave	$t_{W(SCKL)M}$ $t_{W(SCKL)S}$	360 200	— —	ns ns
6	Data Setup Time (Inputs) Master Slave	$t_{SU(M)}$ $t_{SU(S)}$	100 100	— —	ns ns
7	Data Hold Time (Inputs) Master Slave	$t_{H(M)}$ $t_{H(S)}$	100 100	— —	ns ns
8	Slave Access Time (Time to Data Active from High-Impedance State)	$t_A$	0	125	ns
9	Slave Disable Time (Hold Time to High-Impedance State)	$t_{DIS}$	—	250	ns
10	Data Valid Master (Before Capture Edge) Slave (After Enable Edge)‡	$t_{V(M)}$ $t_{V(S)}$	0.25 —	— 250	$t_{CYC(M)}$ ns
11	Data Hold Time (Outputs) Master (After Capture Edge) Slave (After Enable Edge)	$t_{HO(M)}$ $t_{HO(S)}$	0.25 0	— —	$t_{CYC(M)}$ ns
12	Rise Time (20% $V_{DD}$ to 70% $V_{DD}$ , $C_L = 200\text{ pF}$ ) SPI Outputs (SCK, MOSI, and MISO) SPI Inputs (SCK, MOSI, MISO, and SS)	$t_{RM}$ $t_{RS}$	— —	100 2.0	ns $\mu\text{s}$
13	Fall Time (70% $V_{DD}$ to 20% $V_{DD}$ , $C_L = 200\text{ pF}$ ) SPI Outputs (SCK, MOSI, and MISO) SPI Inputs (SCK, MOSI, MISO, and SS)	$t_{FM}$ $t_{FS}$	— —	100 2.0	ns $\mu\text{s}$

† Signal production depends on software.

‡ Assumes 200 pF load on all SPI pins.
