

PREFACE

This manual defines the functionality of the RCPU for use by software and hardware developers. The RCPU is a PowerPC-based processor used in the Motorola MPC500 family of microcontrollers.

Audience

This manual is intended for system software and hardware developers and applications programmers who want to develop products for RCPU-based microcontroller systems. It is assumed that the reader understands operating systems, microprocessor and microcontroller system design, and the basic principles of RISC processing.

Additional Reading

This section lists additional reading that provides background to or supplements the information in this manual.

- John L. Hennessy and David A. Patterson, *Computer Architecture: A Quantitative Approach*, Morgan Kaufmann Publishers, Inc., San Mateo, CA
- *PowerPC Microprocessor Family: the Programming Environments*, MPCFPE/AD (Motorola order number)
- *IEEE Standard for Binary Floating-Point Arithmetic* (ANSI/IEEE Standard 754-1985), published by the Institute of Electrical and Electronics Engineers, Inc., New York, NY
- Motorola technical summaries and device manuals for individual RCPU-based microcontrollers; and module reference manuals (such as this manual) that describe the operation of the individual modules in RCPU-based MCUs in detail. Refer to <http://www.mcu.motsps.com> for a comprehensive listing of available documentation.

Conventions

This document uses the following notational conventions:

ACTIVE_HIGH	Names for signals that are active high are shown in uppercase text without an overbar. Signals that are active high are referred to as asserted when they are high and negated when they are low.
<u>ACTIVE_LOW</u>	A bar over a signal name indicates that the signal is active low. Active-low signals are referred to as asserted (active) when they are low and negated when they are high.
mnemonics	Instruction mnemonics are shown in lowercase bold.
<i>italics</i>	Italics indicate variable command parameters, for example,

	bcctrx
0x0F	Hexadecimal numbers
0b0011	Binary numbers
rA 0	The contents of a specified GPR or the value 0.
REG[FIELD]	Abbreviations or acronyms for registers are shown in uppercase text. Specific bit fields or ranges are shown in brackets.
x	In certain contexts, such as a signal encoding, this indicates a don't care. For example, if a field is binary encoded 0bx001, the state of the first bit is a don't care.

Nomenclature

Logic level one is the voltage that corresponds to Boolean true (1) state.

Logic level zero is the voltage that corresponds to Boolean false (0) state.

To **set** a bit or bits means to establish logic level one on the bit or bits.

To **clear** a bit or bits means to establish logic level zero on the bit or bits.

A signal that is **asserted** is in its active logic state. An active low signal changes from logic level one to logic level zero when asserted, and an active high signal changes from logic level zero to logic level one.

A signal that is **negated** is in its inactive logic state. An active low signal changes from logic level zero to logic level one when negated, and an active high signal changes from logic level one to logic level zero.

LSB means least significant bit or bits. **MSB** means most significant bit or bits. References to low and high bytes are spelled out.
