

SECTION 7 TIME PROCESSOR UNIT

The time processor unit (TPU) is an intelligent, semi-autonomous microcontroller designed for timing control. Operating simultaneously with the CPU32, the TPU schedules tasks, processes microcode ROM instructions, accesses shared data with the CPU32, and performs input and output functions. **Figure 7-1** is a simplified block diagram of the TPU.

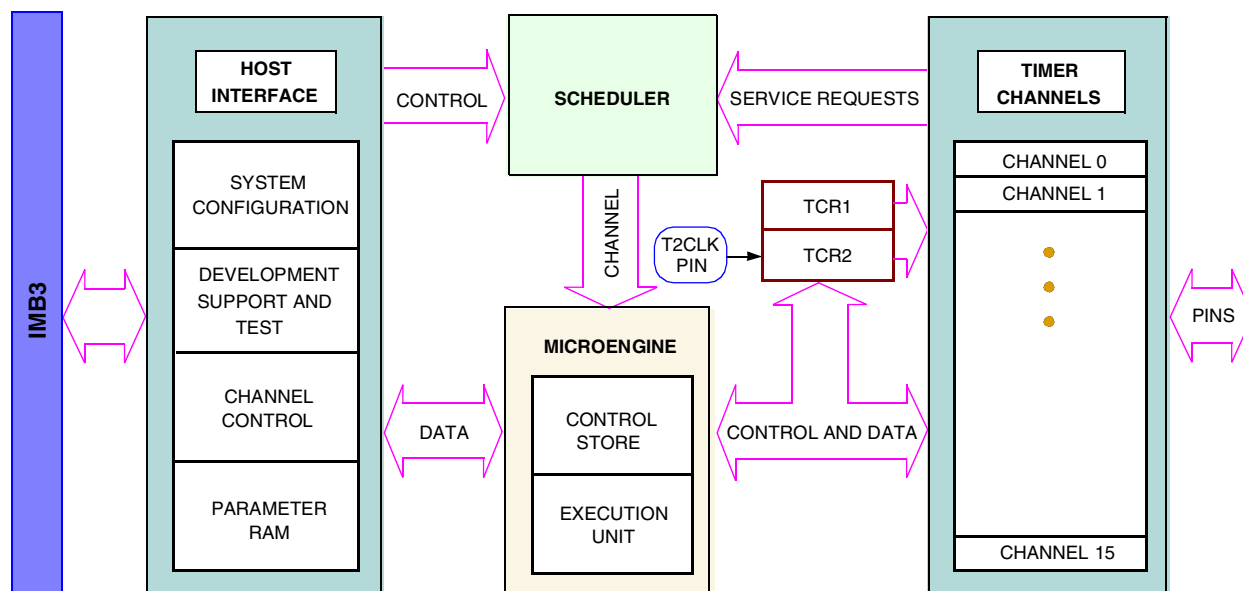

Figure 7-1 TPU Block Diagram

7.1 General

The TPU can be viewed as a special-purpose microcomputer that performs a programmable series of two operations, match and capture. Each occurrence of either operation is called an event. A programmed series of events is called a function. TPU functions replace software functions that would require CPU32 interrupt service. Two sets of microcode ROM functions are currently available for most MCU derivatives with the TPU.

The A mask set (or original mask set) includes the following functions:

- Discrete input/output
- Input capture/input transition counter
- Output compare

- Pulse width modulation
- Synchronized pulse width modulation
- Period measurement with additional transition detect
- Period measurement with missing transition detect
- Position-synchronized pulse generator
- Stepper motor
- Period/pulse width accumulator
- Quadrature decode

The G mask set (or motion control mask set) includes the following functions:

- Table stepper motor
- New input capture/transition counter
- Queued output match
- Programmable time accumulator
- Multichannel pulse width modulation
- Fast quadrature decode
- Universal asynchronous receiver/transmitter
- Brushless motor communication
- Frequency measurement
- Hall effect decode

7.2 TPU Components

The TPU consists of two 16-bit time bases, sixteen independent timer channels, a task scheduler, a microengine, and a host interface. In addition, a dual-ported parameter RAM is used to pass parameters between the module and the CPU32.

7.2.1 Time Bases

Two 16-bit counters provide reference time bases for all output compare and input capture events. Prescalers for both time bases are controlled by the CPU32 via bit fields in the TPU module configuration register (TPUMCR). Timer count registers TCR1 and TCR2 provide access to the current counter values. TCR1 and TCR2 can be read by TPU microcode, but are not directly available to the CPU32. The TCR1 clock is derived from the system clock. The TCR2 clock can be derived from the system clock or from an external clock input via the T2CLK pin.

7.2.2 Timer Channels

The TPU has 16 independent channels, each connected to an MCU pin. The channels have identical hardware. Each channel consists of an event register and pin control logic. The event register contains a 16-bit capture register, a 16-bit compare/match register, and a 16-bit greater-than-or-equal-to comparator. The direction of each pin, either output or input, is determined by the TPU microengine. Each channel can either use the same time base for match and capture, or can use one time base for match and the other for capture.

7.2.3 Scheduler

When a service request is received, the scheduler determines which TPU channel is serviced by the microengine. A channel can request service for one of four reasons: for host service, for a link to another channel, for a match event, or for a capture event. The host system assigns each active channel one of three priorities: high, middle, or low. When multiple service requests are received simultaneously, a priority-scheduling mechanism grants service based on channel number and assigned priority.

7.2.4 Microengine

The microengine is composed of a control store and an execution unit. Control-store ROM holds the microcode for each factory-masked time function. When assigned to a channel by the scheduler, the execution unit executes microcode for a function assigned to that channel by the CPU32. Microcode can also be executed from the TPURAM module instead of the control store. The TPURAM allows emulation and development of custom TPU microcode without the generation of a microcode ROM mask. Refer to [7.3.6 Emulation Support](#) for more information.

7.2.5 Host Interface

The host interface registers allow communication between the CPU32 and the TPU, both before and during execution of a time function. The registers are accessible from the IMB through the TPU bus interface unit. Refer to [7.6 Host Interface Registers](#) and [APPENDIX D REGISTER SUMMARY](#) for register bit/field definitions and address mapping.

7.2.6 Parameter RAM

Parameter RAM occupies 256 bytes at the top of the system address map. Channel parameters are organized as 128 16-bit words. Although all parameter word locations in RAM can be accessed by all channels, only 100 are normally used: channels 0 to 13 use six parameter words, while channels 14 and 15 each use eight parameter words. The parameter RAM address map in [APPENDIX D REGISTER SUMMARY](#) shows how parameter words are organized in memory.

The CPU32 specifies function parameters by writing to the appropriate RAM address. The TPU reads the RAM to determine channel operation. The TPU can also store information to be read by the CPU32 in the parameter RAM. Detailed descriptions of the parameters required by each time function are beyond the scope of this manual. Refer to the [TPU Reference Manual](#) (TPURM/AD) and the Motorola [TPU Literature Package](#) (TPULITPAK/D) for more information.

7.3 TPU Operation

All TPU functions are related to one of the two 16-bit time bases. Functions are synthesized by combining sequences of match events and capture events. Because the primitives are implemented in hardware, the TPU can determine precisely when a match or capture event occurs, and respond rapidly. An event register for each channel provides for simultaneity of match/capture event occurrences on all channels.

When a match or input capture event requiring service occurs, the affected channel generates a service request to the scheduler. The scheduler determines the priority of the request and assigns the channel to the microengine at the first available time. The microengine performs the function defined by the content of the control store or emulation RAM, using parameters from the parameter RAM.

7.3.1 Event Timing

Match and capture events are handled by independent channel hardware. This provides an event accuracy of one time-base clock period, regardless of the number of channels that are active. An event normally causes a channel to request service. The time needed to respond to and service an event is determined by which channels and the number of channels requesting service, the relative priorities of the channels requesting service, and the microcode execution time of the active functions. Worst-case event service time (latency) determines TPU performance in a given application. Latency can be closely estimated. For more information, refer to the [TPU Reference Manual](#) (TPURM/AD)

7.3.2 Channel Orthogonality

Most timer systems are limited by the fixed number of functions assigned to each pin. All TPU channels contain identical hardware and are functionally equivalent in operation, so that any channel can be configured to perform any time function. Any function can operate on the calling channel, and, under program control, on another channel determined by the program or by a parameter. The user controls the combination of time functions.

7.3.3 Interchannel Communication

The autonomy of the TPU is enhanced by the ability of a channel to affect the operation of one or more other channels without CPU32 intervention. Interchannel communication can be accomplished by issuing a link service request to another channel, by controlling another channel directly, or by accessing the parameter RAM of another channel.

7.3.4 Programmable Channel Service Priority

The TPU provides a programmable service priority level to each channel. Three priority levels are available. When more than one channel of a given priority requests service at the same time, arbitration is accomplished according to channel number. To prevent a single high-priority channel from permanently blocking other functions, other service requests of the same priority are performed in channel order after the lowest-numbered, highest-priority channel is serviced.

7.3.5 Coherency

For data to be coherent, all available portions of the data must be identical in age, or must be logically related. As an example, consider a 32-bit counter value that is read and written as two 16-bit words. The 32-bit value is read-coherent only if both 16-bit portions are updated at the same time, and write-coherent only if both portions take

effect at the same time. Parameter RAM hardware supports coherent access of two adjacent 16-bit parameters. The host CPU must use a long-word operation to guarantee coherency.

7.3.6 Emulation Support

Although factory-programmed time functions can perform a wide variety of control tasks, they may not be ideal for all applications. The TPU provides emulation capability that allows the user to develop new time functions. Emulation mode is entered by setting the EMU bit in TPUMCR. In emulation mode, an auxiliary bus connection is made between TPURAM and the TPU, and access to TPURAM via the intermodule bus is disabled. A 9-bit address bus, a 32-bit data bus, and control lines transfer information between the modules. To ensure exact emulation, RAM module access timing remains consistent with access timing of the TPU microcode ROM control store.

To support changing TPU application requirements, Motorola has established a TPU function library. The function library is a collection of TPU functions written for easy assembly in combination with each other or with custom functions. Refer to Motorola Programming Note TPUPN00/D, [Using the TPU Function Library and TPU Emulation Mode](#) for information about developing custom functions and accessing the TPU function library. Refer to the [TPU Reference Manual](#) (TPURM/AD) and the Motorola [TPU Literature Package](#) (TPULITPAK/D) for more information about specific functions.

7.3.7 TPU Interrupts

Each of the TPU channels can generate an interrupt service request. Interrupts for each channel must be enabled by writing to the appropriate control bit in the channel interrupt enable register (CIER). The channel interrupt status register (CISR) contains one interrupt status flag per channel. Time functions set the flags. Setting a flag bit causes the TPU to make an interrupt service request if the corresponding channel interrupt enable bit is set and the interrupt request level is non-zero.

The value of the channel interrupt request level (CIRL) field in the TPU interrupt configuration register (TICR) determines the priority of all TPU interrupt service requests. CIRL values correspond to MCU interrupt request signals $\overline{\text{IRQ}}[7:1]$. $\overline{\text{IRQ}}7$ is the highest-priority request signal; $\overline{\text{IRQ}}1$ has the lowest priority. Assigning a value of %111 to CIRL causes $\overline{\text{IRQ}}7$ to be asserted when a TPU interrupt request is made; lower field values cause corresponding lower-priority interrupt request signals to be asserted. Assigning CIRL a value of %000 disables all interrupts.

The CPU32 recognizes only interrupt requests of a priority greater than the value contained in the interrupt priority (IP) mask in the status register. When the CPU32 acknowledges an interrupt request, the priority of the acknowledged interrupt is written to the IP mask and is driven out onto the IMB address lines.

When the IP mask value driven out on the address lines is the same as the CIRL value, the TPU contends for arbitration priority. The IARB field in TPUMCR contains the TPU arbitration number. Each module that can make an interrupt service request must be assigned a unique non-zero IARB value in order to implement an arbitration scheme.

Arbitration is performed by means of serial assertion of IARB field bit values. The IARB of TPUMCR is initialized to \$0 during reset.

When the TPU wins arbitration, it must respond to the CPU32 interrupt acknowledge cycle by placing an interrupt vector number on the data bus. The vector number is used to calculate displacement into the exception vector table. Vectors are formed by concatenating the 4-bit value of the CIBV field in TICR with the 4-bit number of the channel requesting interrupt service. Since the CIBV field has a reset value of \$0, it must be assigned a value corresponding to the upper nibble of a block of 16 user-defined vector numbers before TPU interrupts are enabled. Otherwise, a TPU interrupt service request could cause the CPU32 to take one of the reserved vectors in the exception vector table.

For more information about the exception vector table, refer to [4.9 Exception Processing](#). Refer to [5.8 Interrupts](#) for further information about interrupts.

7.4 A Mask Set Time Functions

The following paragraphs describe factory-programmed time functions implemented in the A mask set TPU microcode ROM. A complete description of the functions is beyond the scope of this manual. Refer to the [TPU Reference Manual](#) (TPURM/AD) for additional information.

7.4.1 Discrete Input/Output (DIO)

When a pin is used as a discrete input, a parameter indicates the current input level and the previous 15 levels of a pin. Bit 15, the most significant bit of the parameter, indicates the most recent state. Bit 14 indicates the next most recent state, and so on. The programmer can choose one of the three following conditions to update the parameter: 1) when a transition occurs, 2) when the CPU32 makes a request, or 3) when a rate specified in another parameter is matched. When a pin is used as a discrete output, it is set high or low only upon request by the CPU32.

Refer to TPU programming note [Discrete Input/Output \(DIO\) TPU Function](#) (TPUPN18/D) for more information.

7.4.2 Input Capture/Input Transition Counter (ITC)

Any channel of the TPU can capture the value of a specified TCR upon the occurrence of each transition or specified number of transitions and then generate an interrupt request to notify the CPU32. A channel can perform input captures continually, or a channel can detect a single transition or specified number of transitions, then cease channel activity until reinitialization. After each transition or specified number of transitions, the channel can generate a link to a sequential block of up to eight channels. The user specifies a starting channel of the block and the number of channels within the block. The generation of links depends on the mode of operation. In addition, after each transition or specified number of transitions, one byte of the parameter RAM (at an address specified by channel parameter) can be incremented and used as a flag to notify another channel of a transition.

Refer to TPU programming note [Input Capture/Input Transition Counter \(ITC\) TPU Function](#) (TPUPN16/D) for more information.

7.4.3 Output Compare (OC)

The output compare function generates a rising edge, a falling edge, or a toggle of the previous edge in one of three ways:

1. Immediately upon CPU32 initiation, thereby generating a pulse with a length equal to a programmable delay time.
2. At a programmable delay time from a user-specified time.
3. As a continuous square wave. Upon receiving a link from a channel, OC references, without CPU32 interaction, a specifiable period and calculates an offset:

$$\text{OFFSET} = \text{PERIOD} \cdot \text{RATIO}$$

where “RATIO” is a parameter supplied by the user.

This algorithm generates a 50% duty-cycle continuous square wave with each high/low time equal to the calculated offset. Due to offset calculation, there is an initial link time before continuous pulse generation begins.

Refer to TPU programming note [Output Compare \(OC\) TPU Function](#) (TPUPN12/D) for more information.

7.4.4 Pulse-Width Modulation (PWM)

The TPU can generate a pulse-width modulated waveform with any duty cycle from zero to 100% (within the resolution and latency capability of the TPU). To define the PWM, the CPU32 provides one parameter that indicates the period and another parameter that indicates the high time. Updates to one or both of these parameters can direct the waveform change to take effect immediately, or coherently beginning at the next low-to-high transition of the pin.

Refer to TPU programming note [Pulse-Width Modulation \(PWM\) TPU Function](#) (TPUPN17/D) for more information.

7.4.5 Synchronized Pulse-Width Modulation (SPWM)

The TPU generates a PWM waveform in which the CPU32 can change the period and/or high time at any time. When synchronized to a time function on a second channel, the synchronized PWM low-to-high transitions have a time relationship to transitions on the second channel.

Refer to TPU programming note [Synchronized Pulse-Width Modulation \(SPWM\) TPU Function](#) (TPUPN19/D) for more information.

7.4.6 Period Measurement with Additional Transition Detect (PMA)

This function and the following function are used primarily in toothed-wheel speed-sensing applications, such as monitoring rotational speed of an engine. The period

measurement with additional transition detect function allows for a special-purpose 23-bit period measurement. It can detect the occurrence of an additional transition (caused by an extra tooth on the sensed wheel) indicated by a period measurement that is less than a programmable ratio of the previous period measurement.

Once detected, this condition can be counted and compared to a programmable number of additional transitions detected before TCR2 is reset to \$FFFF. Alternatively, a byte at an address specified by a channel parameter can be read and used as a flag. A non-zero value of the flag indicates that TCR2 is to be reset to \$FFFF once the next additional transition is detected.

Refer to TPU programming note [*Period Measurement, Additional Transition Detect \(PMA\) TPU Function*](#) (TPUPN15A/D) for more information.

7.4.7 Period Measurement with Missing Transition Detect (PMM)

Period measurement with missing transition detect allows a special-purpose 23-bit period measurement. It detects the occurrence of a missing transition (caused by a missing tooth on the sensed wheel), indicated by a period measurement that is greater than a programmable ratio of the previous period measurement. Once detected, this condition can be counted and compared to a programmable number of additional transitions detected before TCR2 is reset to \$FFFF. In addition, one byte at an address specified by a channel parameter can be read and used as a flag. A non-zero value of the flag indicates that TCR2 is to be reset to \$FFFF once the next missing transition is detected.

Refer to TPU programming note [*Period Measurement, Missing Transition Detect \(PMM\) TPU Function*](#) (TPUPN15B/D) for more information.

7.4.8 Position-Synchronized Pulse Generator (PSP)

Any channel of the TPU can generate an output transition or pulse, which is a projection in time based on a reference period previously calculated on another channel. Both TCRs are used in this algorithm: TCR1 is internally clocked, and TCR2 is clocked by a position indicator in the user's device. An example of a TCR2 clock source is a sensor that detects special teeth on the flywheel of an automobile using PMA or PMM. The teeth are placed at known degrees of engine rotation; hence, TCR2 is a coarse representation of engine degrees. For example, each count represents some number of degrees.

Up to 15 position-synchronized pulse generator function channels can operate with a single input reference channel executing a PMA or PMM input function. The input channel measures and stores the time period between the flywheel teeth and resets TCR2 when the engine reaches a reference position. The output channel uses the period calculated by the input channel to project output transitions at specific engine degrees. Because the flywheel teeth might be 30 or more degrees apart, a fractional multiplication operation resolves down to the desired degrees. Two modes of operation allow pulse length to be determined either by angular position or by time.

Refer to TPU programming note [*Position-Synchronized Pulse Generator \(PSP\) TPU Function*](#) (TPUPN14/D) for more information.

7.4.9 Stepper Motor (SM)

The stepper motor control algorithm provides for linear acceleration and deceleration control of a stepper motor with a programmable number of step rates of up to 14. Any group of channels, up to eight, can be programmed to generate the control logic necessary to drive a stepper motor.

The time period between steps (P) is defined as:

$$P(r) = K1 - K2 \cdot r$$

where r is the current step rate (1–14), and K1 and K2 are supplied as parameters.

After providing the desired step position in a 16-bit parameter, the CPU32 issues a step request. Next, the TPU steps the motor to the desired position through an acceleration/deceleration profile defined by parameters. The parameter indicating the desired position can be changed by the CPU32 while the TPU is stepping the motor. This algorithm changes the control state every time a new step command is received.

A 16-bit parameter initialized by the CPU32 for each channel defines the output state of the associated pin. The bit pattern written by the CPU32 defines the method of stepping, such as full stepping or half stepping. With each transition, the 16-bit parameter rotates one bit. The period of each transition is defined by the programmed step rate.

Refer to TPU programming note [*Stepper Motor \(SM\) TPU Function*](#) (TPUPN13/D) for more information.

7.4.10 Period/Pulse-Width Accumulator (PPWA)

The period/pulse-width accumulator algorithm accumulates a 16-bit or 24-bit sum of either the period or the pulse width of an input signal over a programmable number of periods or pulses (from one to 255). After an accumulation period, the algorithm can generate a link to a sequential block of up to eight channels. The user specifies a starting channel of the block and number of channels within the block. Generation of links depends on the mode of operation. Any channel can be used to measure an accumulated number of periods of an input signal. A maximum of 24 bits can be used for the accumulation parameter. From one to 255 period measurements can be made and summed with the previous measurement(s) before the TPU interrupts the CPU, allowing instantaneous or average frequency measurement, and the latest complete accumulation (over the programmed number of periods).

The pulse width (high-time portion) of an input signal can be measured (up to 24 bits) and added to a previous measurement over a programmable number of periods (one to 255). This provides an instantaneous or average pulse-width measurement capability, allowing the latest complete accumulation (over the specified number of periods) to always be available in a parameter. By using the output compare function in conjunction with PPWA, an output signal can be generated that is proportional to a

specified input signal. The ratio of the input and output frequency is programmable. One or more output signals with different frequencies, yet proportional and synchronized to a single input signal, can be generated on separate channels.

Refer to TPU programming note [*Period/Pulse-Width Accumulator \(PPWA\) TPU Function*](#) (TPUPN11/D) for more information.

7.4.11 Quadrature Decode (QDEC)

The quadrature decode function uses two channels to decode a pair of out-of-phase signals in order to present the CPU32 with directional information and a position value. It is particularly suitable for use with slotted encoders employed in motor control. The function derives full resolution from the encoder signals and provides a 16-bit position counter with rollover/under indication via an interrupt.

The counter in parameter RAM is updated when a valid transition is detected on either one of the two inputs. The counter is incremented or decremented depending on the lead/lag relationship of the two signals at the time of servicing the transition. The user can read or write the counter at any time. The counter is free running, overflowing to \$0000 or underflowing to \$FFFF depending on direction.

The QDEC function also provides a time stamp referenced to TCR1 for every valid signal edge and the ability for the host CPU to obtain the latest TCR1 value. This feature allows position interpolation by the host CPU between counts at very slow count rates.

Refer to TPU programming note [*Quadrature Decode \(QDEC\) TPU Function*](#) (TPUPN20/D) for more information.

7.5 G Mask Set Time Functions

The following paragraphs describe factory-programmed time functions implemented in the motion control microcode ROM. A complete description of the functions is beyond the scope of this manual.

Refer to the [*TPU Reference Manual*](#) (TPURM/AD) for additional information.

7.5.1 Table Stepper Motor (TSM)

The TSM function provides for acceleration and deceleration control of a stepper motor with a programmable number of step rates up to 58. TSM uses a table in parameter RAM, rather than an algorithm, to define the stepper motor acceleration profile, allowing the user to fully define the profile. In addition, a slew rate parameter allows fine control of the terminal running speed of the motor independent of the acceleration table. The CPU need only write a desired position, and the TPU accelerates, slews, and decelerates the motor to the required position. Full and half step support is provided for two-phase motors. In addition, a slew rate parameter allows fine control of the terminal running speed of the motor independent of the acceleration table.

Refer to TPU programming note [*Table Stepper Motor \(TSM\) TPU Function*](#) (TPUPN04/D) for more information.

7.5.2 New Input Capture/Transition Counter (NITC)

Any channel of the TPU can capture the value of a specified TCR or any specified location in parameter RAM upon the occurrence of each transition or specified number of transitions, and then generate an interrupt request to notify the CPU32. The times of the most recent two transitions are maintained in parameter RAM. A channel can perform input captures continually, or a channel can detect a single transition or specified number of transitions, ceasing channel activity until reinitialization. After each transition or specified number of transitions, the channel can generate a link to other channels.

Refer to TPU programming note [*New Input Capture/Transition Counter \(NITC\) TPU Function*](#) (TPUPN08/D) for more information.

7.5.3 Queued Output Match (QOM)

QOM can generate single or multiple output match events from a table of offsets in parameter RAM. Loop modes allow complex pulse trains to be generated once, a specified number of times, or continuously. The function can be triggered by a link from another TPU channel. In addition, the reference time for the sequence of matches can be obtained from another channel. QOM can generate pulse width modulated waveforms, including waveforms with high times of 0% or 100%. QOM also allows a TPU channel to be used as a discrete output pin.

Refer to TPU programming note [*Queued Output Match \(QOM\) TPU Function*](#) (TPUPN01/D) for more information.

7.5.4 Programmable Time Accumulator (PTA)

PTA accumulates a 32-bit sum of the total high time, low time, or period of an input signal over a programmable number of periods or pulses. The accumulation can start on a rising or falling edge. After the specified number of periods or pulses, PTA generates an interrupt request and optionally generates links to other channels.

From one to 255 period measurements can be made and summed with the previous measurement(s) before the TPU interrupts the CPU32, providing instantaneous or average frequency measurement capability, and the latest complete accumulation (over the programmed number of periods).

Refer to TPU programming note [*Programmable Time Accumulator \(PTA\) TPU Function*](#) (TPUPN06/D) for more information.

7.5.5 Multichannel Pulse-Width Modulation (MCPWM)

MCPWM generates pulse-width modulated outputs with full 0% to 100% duty cycle range independent of other TPU activity. This capability requires two TPU channels plus an external gate for one PWM channel. (A simple one-channel PWM capability is supported by the QOM function).

Multiple PWMs generated by MCPWM have two types of high time alignment: edge aligned and center aligned. Edge aligned mode uses $n + 1$ TPU channels for n PWMs; center aligned mode uses $2n + 1$ channels. Center aligned mode allows a user-defined “dead time” to be specified so that two PWMs can be used to drive an H-bridge without destructive current spikes. This feature is important for motor control applications.

Refer to TPU programming note [*Multichannel Pulse-Width Modulation \(MCPWM\) TPU Function*](#) (TPUPN05/D) for more information.

7.5.6 Fast Quadrature Decode (FQD)

FQD is a position feedback function for motor control. It decodes the two signals from a slotted encoder to provide the CPU32 with a 16-bit free running position counter. FQD incorporates a “speed switch” which disables one of the channels at high speed, allowing faster signals to be decoded. A time stamp is provided on every counter update to allow position interpolation and better velocity determination at low speed or when low resolution encoders are used. The third index channel provided by some encoders is handled by the NITC function.

Refer to TPU programming note [*Fast Quadrature Decode \(FQD\) TPU Function*](#) (TPUPN02/D) for more information.

7.5.7 Universal Asynchronous Receiver/Transmitter (UART)

The UART function uses one or two TPU channels to provide asynchronous serial communication. Data word length is programmable from one to 14 bits. The function supports detection or generation of even, odd, and no parity. Baud rate is freely programmable and can be higher than 100 Kbaud. Eight bidirectional UART channels running in excess of 9600 baud can be implemented.

Refer to TPU programming note [*Universal Asynchronous Receiver/Transmitter \(UART\) TPU Function*](#) (TPUPN07/D) for more information.

7.5.8 Brushless Motor Commutation (COMM)

This function generates the phase commutation signals for a variety of brushless motors, including three-phase brushless DC motors. It derives the commutation state directly from the position decoded in FQD, thus eliminating the need for hall effect sensors.

The state sequence is implemented as a user-configurable state machine, thus providing a flexible approach with other general applications. An offset parameter is provided to allow all the switching angles to be advanced or retarded on the fly by the CPU32. This feature is useful for torque maintenance at high speeds.

Refer to TPU programming note [*Brushless Motor Commutation \(COMM\) TPU Function*](#) (TPUPN09/D) for more information.

7.5.9 Frequency Measurement (FQM)

FQM counts the number of input pulses to a TPU channel during a user-defined window period. The function has single shot and continuous modes. No pulses are lost between sample windows in continuous mode. The user selects whether to detect pulses on the rising or falling edge. This function is intended for high speed measurement; measurement of slow pulses with noise rejection can be made with PTA.

Refer to TPU programming note [Frequency Measurement \(FQM\) TPU Function](#) (TPUPN03/D) for more information.

7.5.10 Hall Effect Decode (HALLD)

This function decodes the sensor signals from a brushless motor, along with a direction input from the CPU32, into a state number. The function supports two- or three-sensor decoding. The decoded state number is written into a COMM channel, which outputs the required commutation drive signals. In addition to brushless motor applications, the function can have more general applications, such as decoding option switches.

Refer to TPU programming note [Hall Effect Decode \(HALLD\) TPU Function](#) (TPUPN10/D) for more information.

7.6 Host Interface Registers

The TPU memory map contains three groups of registers:

- System configuration registers
- Channel control and status registers
- Development support and test verification registers

All registers except the channel interrupt status register (CISR) must be read or written by means of word accesses. The address space of the TPU memory map occupies 512 bytes. Unused registers within the 512-byte address space return zeros when read.

7.6.1 System Configuration Registers

The TPU configuration control registers, TPUMCR and TICR, determine the value of the prescaler, perform emulation control, specify whether the external TCR2 pin functions as a clock source or as gate of the DIV8 clock for TCR2, and determine interrupt request level and interrupt vector number assignment. Refer to [APPENDIX D REGISTER SUMMARY](#) for more information about TPUMCR and TICR.

7.6.1.1 Prescaler Control for TCR1

Timer count register one (TCR1) is clocked from the output of a prescaler. Two fields in TPUMCR control TCR1. The prescaler's input is the internal TPU system clock divided by either 4 or 32, depending on the value of the PSCK bit. The prescaler divides this input by 1, 2, 4, or 8, depending on the value of TCR1P. Channels using TCR1 have the capability to resolve down to the TPU system clock divided by 4. Refer to [Figure 7-2](#) and [Table 7-1](#).

TPU PRE BLOCK 1

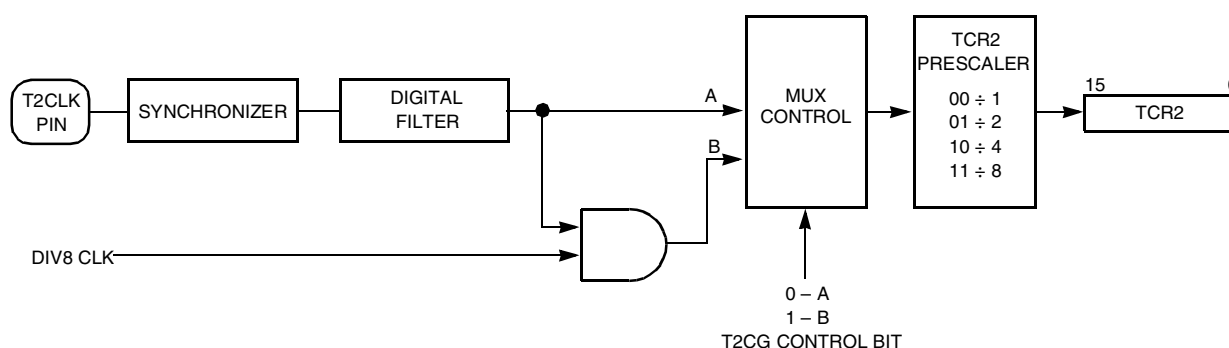

Figure 7-2 TCR1 Prescaler Control

Table 7-1 TCR1 Prescaler Control

		PSCK = 0		PSCK = 1	
TCR1 Prescaler	Divide By	Number of Clocks	Rate at 20.97 MHz	Number of Clocks	Rate at 20.97 MHz
00	1	32	1.6 μ s	4	200 ns
01	2	64	3.2 μ s	8	400 ns
10	4	128	6.4 μ s	16	0.8 μ s
11	8	256	12.8 μ s	32	1.6 μ s

7.6.1.2 Prescaler Control for TCR2

Timer count register two (TCR2), like TCR1, is clocked from the output of a prescaler. The T2CG bit in TPUMCR determines whether the T2CLK pin functions as an external clock source for TCR2 or as the gate in the use of TCR2 as a gated pulse accumulator. The function of the T2CG bit is shown in [Figure 7-3](#).

TPU PRE BLOCK 2

Figure 7-3 TCR2 Prescaler Control

When T2CG is set, the external TCR2 pin functions as a gate of the DIV8 clock (the TPU system clock divided by eight). In this case, when the external TCR2 pin is low, the DIV8 clock is blocked, preventing it from incrementing TCR2. When the external TCR2 pin is high, TCR2 is incremented at the frequency of the DIV8 clock. When T2CG is cleared, an external clock from the TCR2 pin, which has been synchronized and fed through a digital filter, increments TCR2.

The TCR2 field in TPUMCR specifies the value of the prescaler: 1, 2, 4, or 8. Channels using TCR2 have the capability to resolve down to the TPU system clock divided by eight. [Table 7-2](#) is a summary of prescaler output.

Table 7-2 TCR2 Prescaler Control

TCR2 Prescaler	Divide By	Internal Clock Divided By	External Clock Divided By
00	1	8	1
01	2	16	2
10	4	32	4
11	8	64	8

7.6.1.3 Emulation Control

Asserting the EMU bit in TPUMCR places the TPU in emulation mode. In emulation mode, the TPU executes microinstructions from TPURAM exclusively. Access to the TPURAM module through the IMB is blocked, and the TPURAM module is dedicated for use by the TPU. After reset, EMU can be written only once.

7.6.1.4 Low-Power Stop Control

If the STOP bit in TPUMCR is set, the TPU shuts down its internal clocks, shutting down the internal microengine. TCR1 and TCR2 cease to increment and retain the last value before the stop condition was entered. The TPU asserts the stop flag (STF) in TPUMCR to indicate that it has stopped.

7.6.2 Channel Control Registers

The channel control and status registers enable the TPU to control channel interrupts, assign time functions to be executed on a specified channel, or select the mode of operation or the type of host service request for the time function specified. Refer to [Table 7-4](#).

7.6.2.1 Channel Interrupt Enable and Status Registers

The channel interrupt enable register (CIER) allows the CPU32 to enable or disable the ability of individual TPU channels to request interrupt service. Setting the appropriate bit in the register enables a channel to make an interrupt service request; clearing a bit disables the interrupt.

The channel interrupt status register (CISR) contains one interrupt status flag per channel. Time functions specify via microcode when an interrupt flag is set. Setting a flag causes the TPU to make an interrupt service request if the corresponding CIER bit is set and the CIRL field has a non-zero value. To clear a status flag, read CISR, then write a zero to the appropriate bit. CISR is the only TPU register that can be accessed on a byte basis.

7.6.2.2 Channel Function Select Registers

Encoded 4-bit fields within the channel function select registers specify one of 16 time functions to be executed on the corresponding channel. Encodings for predefined functions in the TPU ROM are found in [Table 7-3](#).

Table 7-3 TPU Function Encodings

A Mask Set		G Mask Set	
Function Name	Function Code	Function Name	Function Code
PPWA Period/pulse width accumulator	\$F	PTA Programmable time accumulator	\$F
OC Output compare	\$E	QOM Queued output match	\$E
SM Stepper motor	\$D	TSM Table stepper motor	\$D
PSP Position-synchronized pulse generator	\$C	FQM Frequency measurement	\$C
PMA/PMM Period measurement with additional/missing transition detect	\$B	UART Universal asynchronous receiver/transmitter	\$B
ITC Input capture/input transition counter	\$A	NITC New input transition counter	\$A
PWM Pulse width modulation	\$9	COMM Multiphase motor commutation	\$9
DIO Discrete input/output	\$8	HALLD Hall effect decode	\$8
SPWM Synchronized pulse width modulation	\$7	—	—
QDEC Quadrature decode	\$6	—	—

7.6.2.3 Host Sequence Registers

The host sequence field selects the mode of operation for the time function selected on a given channel. The meaning of the host sequence bits depends on the time function specified. Refer to [Table 7-4](#), which is a summary of the host sequence and host service request bits for each time function. Refer to the [TPU Reference Manual](#) (TPURM/AD) and the Motorola [TPU Literature Package](#) (TPULITPAK/D) for more information.

7.6.2.4 Host Service Registers

The host service request field selects the type of host service request for the time function selected on a given channel. The meaning of the host service request bits is determined by time function microcode. Refer to the [TPU Reference Manual](#) (TPURM/AD) and the Motorola [TPU Literature Package](#) (TPULITPAK/D) for more information.

A host service request field of %00 signals the CPU that service is completed and that there are no further pending host service requests. The host can request service on a channel by writing the corresponding host service request field to one of three non-zero states. It is imperative for the CPU to monitor the host service request register and wait until the TPU clears the service request for a channel before changing any parameters or issuing a new service request to the channel.

7.6.2.5 Channel Priority Registers

The channel priority registers (CPR1, CPR2) assign one of three priority levels to a channel or disable the channel. [Table 7-4](#) indicates the number of time slots guaranteed for each channel priority encoding.

Table 7-4 Channel Priority Encodings

CHX[1:0]	Service	Guaranteed Time Slots
00	Disabled	—
01	Low	1 out of 7
10	Middle	2 out of 7
11	High	4 out of 7

7.6.3 Development Support and Test Registers

These registers are used for custom microcode development or for factory test. Describing the use of these registers is beyond the scope of this manual. Register descriptions are provided in [APPENDIX D REGISTER SUMMARY](#). Refer to the [TPU Reference Manual](#) (TPURM/AD) for more information.
