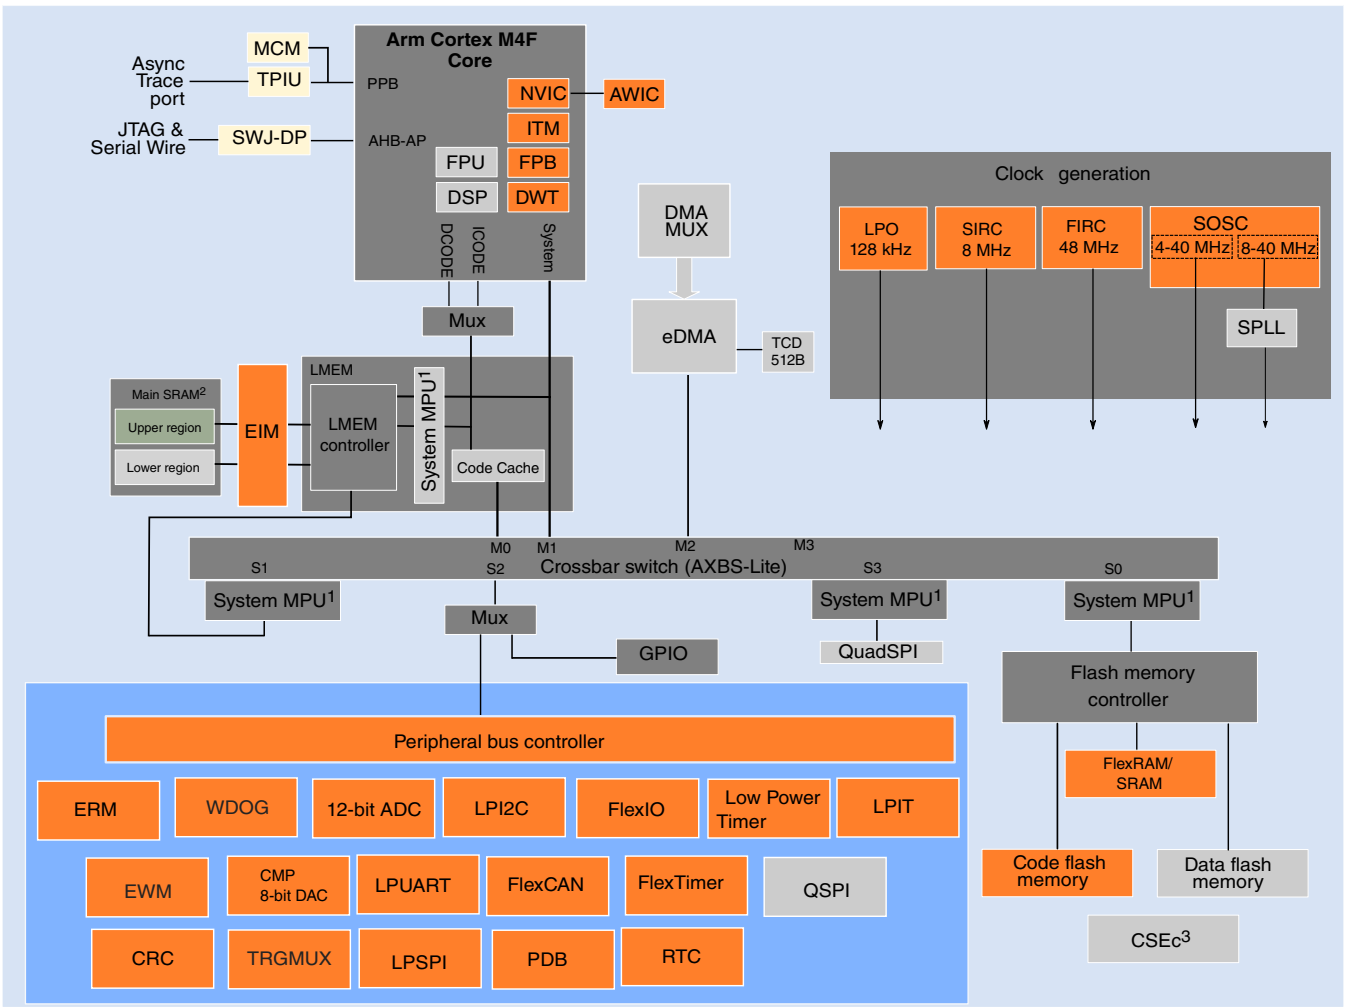
1 Block diagram

The figure below shows a superset high level architecture block diagram of the device. Other devices within the family have a subset of the features. See Feature comparison for chip specific values.



1: On this device, NXP's system MPU implements the safety mechanisms to prevent masters from accessing restricted memory regions. This system MPU provides memory protection at the level of the Crossbar Switch. Each Crossbar master (Core, DMA) can be assigned different access rights to each protected memory region. The Arm M4 core version in this family does not integrate the Arm Core MPU, which would concurrently monitor only core-initiated memory accesses. In this document, the term MPU refers to NXP's system MPU.

2: For the device-specific sizes, see the "On-chip SRAM sizes" table in the "Memories and Memory Interfaces" chapter of the MWCT101xS Series Reference Manual.

3: CSEc (Security) or EEPROM writes/erase will trigger error flags in HSRUN mode (112 MHz) because this use case is not allowed to execute simultaneously. The device needs to switch to RUN mode (80 MHz) to execute CSEc (Security) or EEPROM writes/erase.

4 General

4.1 Absolute maximum ratings

NOTE

- Functional operating conditions appear in the DC electrical characteristics. Absolute maximum ratings are stress ratings only, and functional operation at the maximum values is not guaranteed. See footnotes in the following table for specific conditions.
- Stress beyond the listed maximum values may affect device reliability or cause permanent damage to the device.
- All the limits defined in the datasheet specification must be honored together and any violation to any one or more will not guarantee desired operation.
- Unless otherwise specified, all maximum and minimum values in the datasheet are across process, voltage, and temperature.

Table 1. Absolute maximum ratings

Symbol	Parameter	Conditions[1]	Min	Max	Unit
V_{DD}[2]	2.7 V - 5. 5V input supply voltage	—	-0.3	5.8 [3]	V
V_{REFH}	3.3 V / 5.0 V ADC high reference voltage	—	-0.3	5.8 [3]	V
$I_{INJPAD\_DC\_ABS}$[4]	Continuous DC input current (positive / negative) that can be injected into an I/O pin	—	-3	+3	mA
V_{IN_DC}	Continuous DC Voltage on any I/O pin with respect to V_{SS}	—	-0.8	5.8[5]	V
$I_{INJSUM\_DC\_ABS}$	Sum of absolute value of injected currents on all the pins (Continuous DC limit)	—	—	30	mA
T_{ramp}[6]	ECU supply ramp rate	—	0.5 V/min	500 V/ms	—
T_{ramp_MCU}[7]	MCU supply ramp rate	—	0.5 V/min	100 V/ms	—
T_A[8]	Ambient temperature	—	-40	125	°C
T_{STG}	Storage temperature	—	-55	165	°C
$V_{IN\_TRANSIENT}$	Transient overshoot voltage allowed on I/O pin beyond $V_{IN\_DC\ limit}$	—	—	6.8 [9]	V

1. All voltages are referred to V_{SS} unless otherwise specified.
2. As V_{DD} varies between the minimum value and the absolute maximum value the analog characteristics of the I/O and the ADC will both change. See section I/O parameters and ADC electrical specifications respectively for details.
3. 60 s lifetime – No restrictions i.e. The part can switch.

   10 hours lifetime – Device in reset i.e. The part cannot switch.

4. When input pad voltage levels are close to V_{DD} or V_{SS}, practically no current injection is possible.
5. While respecting the maximum current injection limit
6. This is the Electronic Control Unit (ECU) supply ramp rate and not directly the MCU ramp rate. Limit applies to both maximum absolute maximum ramp rate and typical operating conditions.
7. This is the MCU supply ramp rate, and the ramp rate assumes that the HW design guidelines in AN5426 are followed. Limit applies to both maximum absolute maximum ramp rate and typical operating conditions.
8. T_J (Junction temperature)=135 °C. Assumes T_A=125 °C for RUN mode

   T_J (Junction temperature)=125 °C. Assumes TA=105 °C for HSRUN mode

   - Assumes maximum θJA for 2s2p board. See Thermal characteristics
9. 60 seconds lifetime; device in reset (no outputs enabled/toggling)

4.2 Voltage and current operating requirements

NOTE

Device functionality is guaranteed up to the LVR assert level; however, electrical performance of 12-bit ADC, CMP with 8-bit DAC, IO electrical characteristics, and communication modules electrical characteristics would be degraded when voltage drops below 2.7 V

Table 2. Voltage and current operating requirements 1

Symbol	Description	Min.	Max.	Unit	Notes
V_{DD}[2]	Supply voltage	2.7[3]	5.5	V	4
V_{DD_OFF}	Voltage allowed to be developed on V_{DD} pin when it is not powered from any external power supply source.	0	0.1	V	
V_{DDA}	Analog supply voltage	2.7	5.5	V	4
$V_{DD} – V_{DDA}$	V_{DD}-to-V_{DDA} differential voltage	– 0.1	0.1	V	4
V_{REFH}	ADC reference voltage high	2.7	V_{DDA} + 0.1	V	5
V_{REFL}	ADC reference voltage low	-0.1	0.1	V	
V_{ODPU}	Open drain pullup voltage level	V_{DD}	V_{DD}	V	6
$I_{INJPAD\_DC\_OP}$[7]	Continuous DC input current (positive / negative) that can be injected into an I/O pin	-3	+3	mA	
$I_{INJSUM\_DC\_OP}$	Continuous total DC input current that can be injected across all I/O pins such that there's no degradation in accuracy of analog modules: ADC and ACMP (See section Analog Modules)	—	30	mA	

1. Typical conditions assumes V_{DD} = V_{DDA} = V_{REFH} = 5 V, temperature = 25 °C and typical silicon process unless otherwise stated.
2. As V_{DD} varies between the minimum value and the absolute maximum value the analog characteristics of the I/O and the ADC will both change. See section I/O parameters and ADC electrical specifications respectively for details.
3. MWCT1016S will operate from 2.7 V when executing from internal FIRC. When the PLL is engaged MWCT1016S is guaranteed to operate from 2.97 V. All other MWCT101xS family devices operate from 2.7 V in all modes.
4. V_{DD} and V_{DDA} must be shorted to a common source on PCB. The differential voltage between V_{DD} and V_{DDA} is for RF-AC only. Appropriate decoupling capacitors to be used to filter noise on the supplies. See application note AN5032 for reference supply design for SAR ADC.

5. V_{REFH} should always be equal to or less than V_{DDA} + 0.1 V and V_{DD} + 0.1 V
6. Open drain outputs must be pulled to V_{DD}.
7. When input pad voltage levels are close to V_{DD} or V_{SS}, practically no current injection is possible.

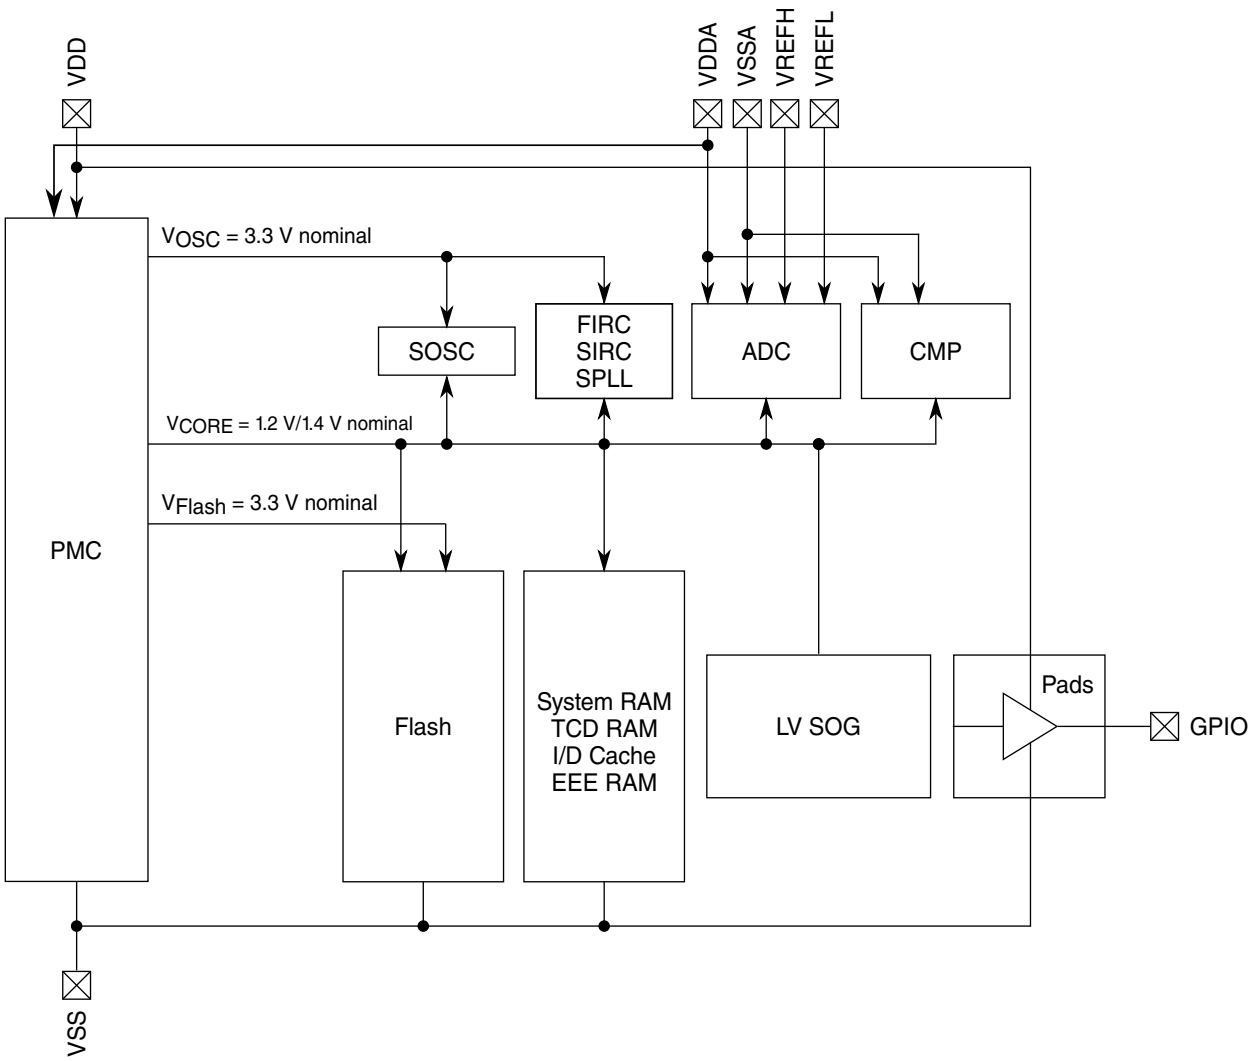
Table 4. Supplies decoupling capacitors 1, 2 (continued)

Symbol	Description	Min. [3]	Typ.	Max.	Unit
C_{DEC} [5, 6, 7]	Recommended decoupling capacitance	70	100	—	nF

1. V_{DD} and V_{DDA} must be shorted to a common source on PCB. The differential voltage between V_{DD} and V_{DDA} is for RF-AC only. Appropriate decoupling capacitors to be used to filter noise on the supplies. See application note AN5032 for reference supply design for SAR ADC. All V_{SS} pins should be connected to common ground at the PCB level.
2. All decoupling capacitors must be low ESR ceramic capacitors (for example X7R type).
3. Minimum recommendation is after considering component aging and tolerance.
4. For improved performance, it is recommended to use 10 µF, 0.1 µF and 1 nF capacitors in parallel.
5. All decoupling capacitors should be placed as close as possible to the corresponding supply and ground pins.
6. Contact your local Field Applications Engineer for details on best analog routing practices.
7. The filtering used for decoupling the device supplies must comply with the following best practices rules:
   - The protection/decoupling capacitors must be on the path of the trace connected to that component.
   - No trace exceeding 1 mm from the protection to the trace or to the ground.
   - The protection/decoupling capacitors must be as close as possible to the input pin of the device (maximum 2 mm).
   - The ground of the protection is connected as short as possible to the ground plane under the integrated circuit.



*Note: VSSA and VSS are shorted at package level

1. Typical current numbers are indicative for typical silicon process and may vary based on the silicon distribution and user configuration. Typical conditions assumes $V_{DD} = V_{DDA} = V_{REFH} = 5$ V, temperature = 25 °C and typical silicon process unless otherwise stated. All output pins are floating and On-chip pulldown is enabled for all unused input pins.

2. This is an average based on the use case described in the Comparator section, whereby the analog sampling is taking place periodically, with a mechanism to only enable the DAC as required. The numbers quoted assumes that only a single ANLCMP is active and the others are disabled
3. Current numbers are for reduced configuration and may vary based on user configuration and silicon process variation.
4. HSRUN mode must not be used at 125°C. Max ambient temperature for HSRUN mode is 105°C.
5. Values mentioned are measured at RUN@80 MHz with peripherals disabled.
6. With PMC_REGSC[CLKBIASDIS] set to 1. See Reference Manual for details.
7. The MWCT1016S data points assume that QuadSPI etc. are inactive.

5 I/O parameters

5.1 AC electrical characteristics

Unless otherwise specified, propagation delays are measured from the 50% to the 50% point, and rise and fall times are measured at the 20% and 80% points, as shown in the following figure.

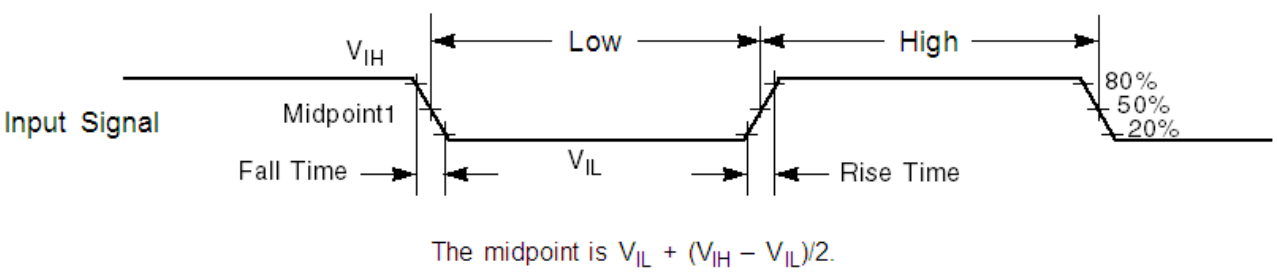

Figure 6. Input signal measurement reference

5.2 General AC specifications

These general purpose specifications apply to all signals configured for GPIO, UART, and timers.

Table 8. General switching specifications

Symbol	Description	Min.	Max.	Unit	Notes
	GPIO pin interrupt pulse width (digital glitch filter disabled) — Synchronous path	1.5	—	Bus clock cycles	1, 2
	GPIO pin interrupt pulse width (digital glitch filter disabled, passive filter disabled) — Asynchronous path	50	—	ns	3
WFRST	$\overline{\text{RESET}}$ input filtered pulse	—	10	ns	4
WNFRST	$\overline{\text{RESET}}$ input not filtered pulse	Maximum of (100 ns, bus clock period)	—	ns	5

1. This is the minimum pulse width that is guaranteed to pass through the pin synchronization circuitry. Shorter pulses may or may not be recognized. In Stop and VLPS modes, the synchronizer is bypassed so shorter pulses can be recognized in that case.
2. The greater of synchronous and asynchronous timing must be met.
3. These pins do not have a passive filter on the inputs. This is the shortest pulse width that is guaranteed to be recognized.
4. Maximum length of $\overline{\text{RESET}}$ pulse which will be filtered by internal filter.
5. Minimum length of $\overline{\text{RESET}}$ pulse, guaranteed not to be filtered by the internal filter. This number depends on bus clock period also. For example, in VLPR mode bus clock is 4 MHz, which make clock period of 250 ns. In this case, minimum pulse width which will cause reset is 250 ns. For faster bus clock frequencies which have clock period less than 100 ns, the minimum pulse width not filtered will be 100 ns.

1. Crystal oscillator circuit provides stable oscillations when g_{mXOSC} > 5 * gm_crit. The gm_crit is defined as:

   gm_crit = 4 * ESR * $(2\pi F)^2$ * $(C_0 + C_L)^2$

   where:

   - g_{mXOSC} is the transconductance of the internal oscillator circuit
   - ESR is the equivalent series resistance of the external crystal
   - F is the external crystal oscillation frequency
   - C_0 is the shunt capacitance of the external crystal
   - C_L is the external crystal total load capacitance. $C_L = C_s + [C_1 * C_2/(C_1+C_2)]$
   - C_s is stray or parasitic capacitance on the pin due to any PCB traces
   - C_1, C_2 external load capacitances on EXTAL and XTAL pins

   See manufacture datasheet for external crystal component values
2. - When low-gain is selected, internal R_F will be selected and external R_F should not be attached.
   - When high-gain is selected, external R_F (1 M Ohm) needs to be connected for proper operation of the crystal. For external resistor, up to 5% tolerance is allowed.
3. The EXTAL and XTAL pins should only be connected to required oscillator components and must not be connected to any other devices.

$t_{quickwrClnup}$	Quick Write Cleanup execution time	—	—	(# of Quick Writes) * 2.0	—	(# of Quick Writes) * 2.0	—	(# of Quick Writes) * 2.0	ms	7

1. All command times assumes 25 MHz or greater flash clock frequency (for synchronization time between internal/external clocks).
2. Maximum times for erase parameters based on expectations at cycling end-of-life.
3. For all EEPROM Emulation terms, the specified timing shown assumes previous record cleanup has occurred. This may be verified by executing FCCOB Command 0x77, and checking FCCOB number 5 contents show 0x00 - No EEPROM issues detected.
4. 1st time EERAM writes after a Reset or SETRAM may incur additional overhead for EEE cleanup, resulting in up to 2× the times shown.
5. Only after the Nth write completes will any data be valid. Emulated EEPROM record scheme cleanup overhead may occur after this point even after a brownout or reset. If power on reset occurs before the Nth write completes, the last valid record set will still be valid and the new records will be discarded.
6. Quick Write times may take up to 550 µs, as additional cleanup may occur when crossing sector boundaries.
7. Time for emulated EEPROM record scheme overhead cleanup. Automatically done after last (Nth) write completes, assuming still powered. Or via SETRAM cleanup execution command is requested at a later point.

NOTE

Under certain circumstances FlexMEM maximum times may be exceeded. In this case the user or application may wait, or assert reset to the FTFC macro to stop the operation.

6.3.1.2 Reliability specifications

Table 22. NVM reliability specifications

Symbol	Description	Min.	Typ.	Max.	Unit	Notes
When using as Program and Data Flash						
$t_{nvmretp1k}$	Data retention after up to 1 K cycles	20	—	—	years	1
$n_{nvmcycp}$	Cycling endurance	1 K	—	—	cycles	2, 3
When using FlexMemory feature: FlexRAM as Emulated EEPROM						
$t_{nvmretee}$	Data retention	5	—	—	years	4
$n_{nvmwree16}$ $n_{nvmwree256}$	Write endurance • EEPROM backup to FlexRAM ratio = 16 • EEPROM backup to FlexRAM ratio = 256	100 K 1.6 M	— —	— —	writes writes	5, 6, 7

1. Data retention period per block begins upon initial user factory programming or after each subsequent erase.
2. Program and Erase for PFlash and DFlash are supported across product temperature specification in Normal Mode (not supported in HSRUN mode).
3. Cycling endurance is per DFlash or PFlash Sector.
4. Data retention period per block begins upon initial user factory programming or after each subsequent erase. Background maintenance operations during normal FlexRAM usage extend effective data retention life beyond 5 years.

5. FlexMemory write endurance specified for 16-bit and/or 32-bit writes to FlexRAM and is supported across product temperature specification in Normal Mode (not supported in HSRUN mode). Greater write endurance may be achieved with larger ratios of EEPROM backup to FlexRAM.
6. For usage of any EEE driver other than the FlexMemory feature, the endurance spec will fall back to the specified endurance value of the D-Flash specification (1K).
7. FlexMemory calculator tool is available at NXP web site for help in estimation of the maximum write endurance achievable at specific EEPROM/FlexRAM ratios. The “In Spec” portions of the online calculator refer to the NVM reliability specifications section of data sheet. This calculator is only applies to the FlexMemory feature.

6.3.2 QuadSPI AC specifications

The following table describes the QuadSPI electrical characteristics.

- Measurements are with maximum output load of 25 pF, input transition of 1 ns and pad configured with fastest slew settings (DSE = 1'b1).
- I/O operating voltage ranges from 2.97 V to 3.6 V
- While doing the mode transition (RUN -> HSRUN or HSRUN -> RUN), the interface should be OFF.
- Add 50 ohm series termination on board in QuadSPI SCK for Flash A to avoid loop back reflection when using in Internal DQS (PAD Loopback) mode.
- QuadSPI trace length should be 3 inches.
- For non-Quad mode of operation if external device doesn’t have pull-up feature, external pull-up needs to be added at board level for non-used pads.
- With external pull-up, performance of the interface may degrade based on load associated with external pull-up.

Table 24. 12-bit ADC operating conditions (continued)

Symbol	Description	Conditions	Min.	Typ.[1]	Max.	Unit	Notes
f_{ADCK}	ADC conversion clock frequency	Normal usage	2	40	50	MHz	3, 4
f_{CONV}	ADC conversion frequency	No ADC hardware averaging.[5] Continuous conversions enabled, subsequent conversion time	46.4	928	1160	Ksps	6, 7
		ADC hardware averaging set to 32. [5] Continuous conversions enabled, subsequent conversion time	1.45	29	36.25	Ksps	6, 7

1. Typical values assume V_{DDA} = 5 V, Temp = 25 °C, f_{ADCK} = 40 MHz, R_{AS}=20 Ω, and C_{AS}=10 nF unless otherwise stated. Typical values are for reference only, and are not tested in production.
2. For packages without dedicated V_{REFH} and V_{REFL} pins, V_{REFH} is internally tied to V_{DDA}, and V_{REFL} is internally tied to V_{SS}. To get maximum performance, reference supply quality should be better than SAR ADC. See application note AN5032 for details.
3. Clock and compare cycle need to be set according to the guidelines mentioned in the *Reference Manual* .
4. ADC conversion will become less reliable above maximum frequency.
5. When using ADC hardware averaging, see the *Reference Manual* to determine the most appropriate setting for AVGS.
6. Numbers based on the minimum sampling time of 275 ns.
7. For guidelines and examples of conversion rate calculation, see the *Reference Manual* or download the ADC calculator tool.

6.4.1.2 12-bit ADC electrical characteristics

NOTE

- ADC performance specifications are documented using a single ADC. For parallel/simultaneous operation of both ADCs, either for sampling the same channel by both ADCs or for sampling different channels by each ADC, some amount of decrease in performance can be expected. Care must be taken to stagger the two ADC conversions, in particular the sample phase, to minimize the impact of simultaneous conversions.
- On reduced pin packages where ADC reference pins are shared with supply pins, ADC analog performance characteristics may be impacted. The amount of variation will be directly impacted by the external PCB layout and hence care must be taken with PCB routing. See AN5426 for details

6. The specifications are with averaging and in standalone mode only. Performance may degrade depending upon device use case scenario. When using ADC averaging, refer to the *Reference Manual* to determine the most appropriate settings for AVGS.
7. For ADC signals adjacent to V_{DD}/V_{SS} or XTAL/EXTAL or high frequency switching pins, some degradation in the ADC performance may be observed.
8. All values guarantee the performance of the ADC for multiple ADC input channel pins. When using ADC to monitor the internal analog parameters, assume minor degradation.
9. All the parameters in the table are given assuming system clock as the clocking source for ADC.

For comparator IN signals adjacent to V_{DD}/V_{SS} or XTAL/EXTAL or switching pins cross coupling may happen and hence hysteresis settings can be used to obtain the desired comparator performance. Additionally, an external capacitor (1nF) should be used to filter noise on input signal. Also, source drive should not be weak (Signal with < 50 K pull up/down is recommended).

- All timing is shown with respect to 20% V_{DD} and 80% V_{DD} thresholds.
- All measurements are with maximum output load of 50 pF, input transition of 1 ns and pad configured with fastest slew setting (DSE = 1).

7.3 General notes for specifications at maximum junction temperature

An estimation of the chip junction temperature, T_J, can be obtained from this equation:

$$T_J = T_A + (R_{\theta JA} \times P_D)$$

where:

- T_A = ambient temperature for the package (°C)
- $R_{\theta JA}$ = junction to ambient thermal resistance (°C/W)
- P_D = power dissipation in the package (W)

The junction to ambient thermal resistance is an industry standard value that provides a quick and easy estimation of thermal performance. Unfortunately, there are two values in common usage: the value determined on a single layer board and the value obtained on a board with two planes. For packages such as the PBGA, these values can be different by a factor of two. Which value is closer to the application depends on the power dissipated by other components on the board. The value obtained on a single layer board is appropriate for the tightly packed printed circuit board. The value obtained on the board with the internal planes is usually appropriate if the board has low power dissipation and the components are well separated.

When a heat sink is used, the thermal resistance is expressed in the following equation as the sum of a junction-to-case thermal resistance and a case-to-ambient thermal resistance:

$$R_{\theta JA} = R_{\theta JC} + R_{\theta CA}$$

where:

- $R_{\theta JA}$ = junction to ambient thermal resistance (°C/W)
- $R_{\theta JC}$ = junction to case thermal resistance (°C/W)
- $R_{\theta CA}$ = case to ambient thermal resistance (°C/W)

$R_{\theta JC}$ is device related and cannot be influenced by the user. The user controls the thermal environment to change the case to ambient thermal resistance, $R_{\theta CA}$. For instance, the user can change the size of the heat sink, the air flow around the device, the interface material, the mounting arrangement on printed circuit board, or change the thermal dissipation on the printed circuit board surrounding the device.

To determine the junction temperature of the device in the application when heat sinks are not used, the Thermal Characterization Parameter (Ψ_{JT}) can be used to determine the junction temperature with a measurement of the temperature at the top center of the package case using this equation:

$$T_J = T_T + (\Psi_{JT} \times P_D)$$

where:

- T_T = thermocouple temperature on top of the package (°C)
- Ψ_{JT} = thermal characterization parameter (°C/W)
- P_D = power dissipation in the package (W)

The thermal characterization parameter is measured per JESD51-2 specification using a 40 gauge type T thermocouple epoxied to the top center of the package case. The thermocouple should be positioned so that the thermocouple junction rests on the package. A small amount of epoxy is placed over the thermocouple junction and over about 1 mm of wire extending from the junction. The thermocouple wire is placed flat against the package case to avoid measurement errors caused by cooling effects of the thermocouple wire.
