

## Rad-Hard 32 bit SPARC V8 Reconfigurable Processor

## DATASHEET

## Features

- SPARC V8 High Performance Low-power 32-bit processor core
  - ATF697F Sparc v8 processor
  - LEON2-FT 1.0.9.16.1 compliant
  - 8 Register Windows
  - Advanced Architecture
    - 5 Stage Pipeline
    - 32 kbyte 4-way associative instruction cache
    - 16 kbyte 2-way associative data cache
- Integrated 32/64-bit IEEE 754 Floating-point Unit
- Reconfigurable Unit
  - ATF697FF SRAM FPGA
  - 280K equivalent ASIC gates
  - 14400 cells
  - Unlimited reprogrammability
  - SEE hardened cells
  - No need for Triple Modular Redundancy (TMR)
  - FreeRAM™
    - 115200 Bits of Distributed RAM
    - 32x4 RAM blocks organization
    - Independent of logic cells
    - Single/Dual Port capability
  - Flexible Configuration modes
  - Master/Slave Capability
  - Serial Capability
  - Flexible clock management
    - 8 Global Clocks
    - 1 Fast Clock
  - Configuration Security Management
    - Check of the data during FPGA configuration
    - Self Integrity Check (SIC) of the configuration during FPGA operation
- Flexible Memory Interface
  - PROM Controller
  - SRAM Controller
  - SDRAM Controller
- Timers
  - Two 32-bit Timers
  - Watchdog Timer

- Two 8-bit UARTs
- Interrupt Controller with 8 External Programmable Inputs
- General Purpose Interface
  - 32 Parallel I/O Interface
  - 140 Configurable Cold Sparring and PCI Compliant I/Os
- 4 LVDS transceivers and 4 LVDS receivers
- Debug and Test Facilities
  - Debug Support Unit (DSU) for Trace and Debug
  - Four Hardware Watchpoints
- Operating range
  - Voltages
    - 3.3V +/-0.30V for I/O
    - 1.8V +/-0.15V for Core
    - 1.25V +/-0.15V for LVDS reference
  - Temperature
    - -55°C to 125°C
- Clocks:
  - Processor : 0 MHz up to 100 MHz
  - Reconfigurable Unit : 0 MHz up to 50 MHz
- Performance:
  - 86MIPS (Dhrystone 2.1)
  - 23MFLOPS (Whetstone)
- Package MQFPT 352
- Mass: 30g
- Radiation performances:
  - RHA capability of 100 krad (Si) according to the MIL-STD-883 method 1019.
  - No single event latch up below a LET threshold of of 60 MeV.cm<sup>2</sup>/mg at 125°C
- Evaluation kit including
  - ATF697FF evaluation board
  - ATF697FF sample

## Description

ATF697FF is a multichip module integrating a 32 bit RISC processor together with a reconfigurable unit. The processor implementation is the European Space Agency (ESA) SPARC V8 LEON2 fault tolerant model also known as AT697F for the Atmel standalone chip. The reconfigurable unit is based on the Atmel 280kgates radiation hardened SRAM-based reprogrammable FPGA also known as ATF697FF.

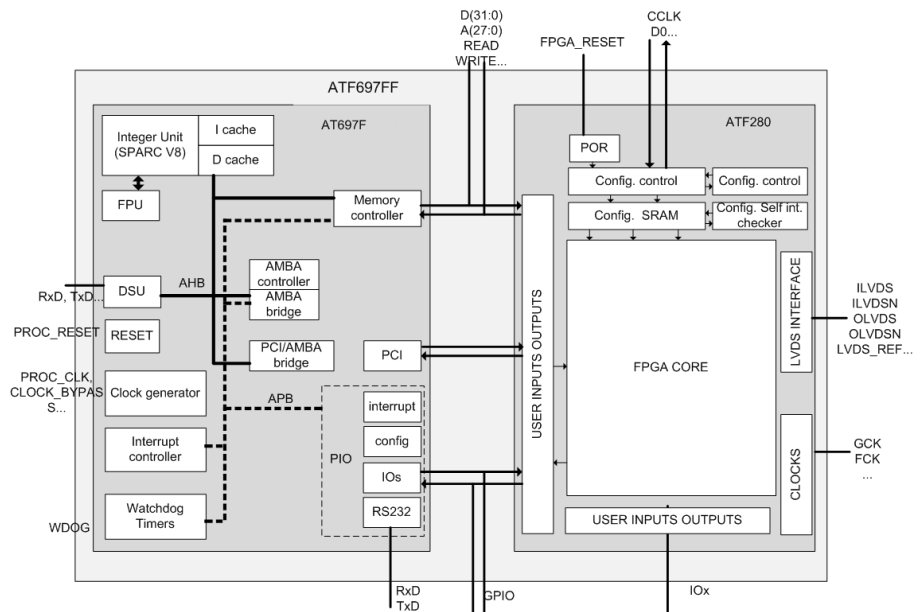

Both the processor unit and the reconfigurable units are manufactured using the Atmel 0.18µm rad-hard AT58KRHA CMOS technology.

The two dies have been especially designed for space application by implementing hardened cells, on-chip concurrent transient and permanent error detection and correction and permanent self integrity check mechanism.

By executing powerful instructions in a single clock cycle, the processor unit achieves throughputs around 1 MIPS per MHz, allowing the system designer to optimize power consumption versus processing speed.

The configurable unit offers a patented distributed 10 ns SEU hardened SRAM capability where the RAM can be used without losing logic resources. Multiple independent, synchronous or asynchronous, dual port or single port RAM functions (FIFO, scratch pad, etc.) can be created using Atmel's macro generator tool. They are organized by blocks of 32x4 bits.

ATF697FF contains an on-chip Integer Unit (IU), a Floating Point Unit (FPU), separate instruction and data caches, hardware multiplier and divider, interrupt controller, debug support unit with trace buffer, two 32-bit timers, Parallel and Serial interfaces, a Watchdog, a reconfigurable unit, a flexible Memory Controller and a 280 Kgates of reconfigurable unit. The configurable unit embeds 8 global clocks, 2 high speed clocks, 4 LVDS interface and 140 cold sparing and PCI compliant programmable I/Os dedicated to the application needs. The communication between the processor and the reconfigurable unit is performed by three different means: the internal PCI interface, GPIO and the EBI interface. ATF697FF only requires memory to be added to form a complete on-board computer.

# 1. Pin description

## 1.1 System Interface

- **PROC\_RESET\*** Processor reset (input)

When asserted, this asynchronous active low input immediately halts and resets the processor and all on-chip peripherals. The processor restarts execution after the 5th rising edge of the clock after PROC\_RESET\* was de-asserted.

- **FPGA\_RESET\*** reconfigurable unit reset (input)

FPGA\_RESET\* is the manual reset of the FPGA. This function reset the configuration download logic. FPGA\_RESET\* is internally pulled up to VCC and is active at a low level. Each time FPGA\_RESET\* is activated, the FPGA enters Manual Reset lifephase.

- **ERROR\*** Processor error (open-drain output with pull-up)

This active low output is asserted when the processor is halted in error mode.

- **WDOG\*** Watchdog timeout (open-drain output with pull-up)

This active low output is asserted when the watchdog timer has expired and remains asserted until the watchdog timer is reloaded with a non-null value.

- **BEXC\*** Bus exception (input)

This active low input is sampled simultaneously with the data during an access to the external memory. If asserted, a memory error is generated.

- **M0, M1, M2** reconfigurable unit configuration mode (Input)

[CFG] The configuration mode pins are used to define the configuration settings of the ATF697FF reconfiguration unit. ATF697FF reconfiguration unit samples the configuration mode pins each time a configuration clear cycle is ended.

**Caution:** The mode pins should not be changed during power-on-reset or manual reset.

- **CCLK** – Reconfigurable unit configuration clock (bi-directional)

CCLK function provides the clock signal used by the configuration logic. Depending on the mode used for configuration download procedure, CCLK function is configured as input or output. For slave mode, the CCLK is configured as an input whereas for master mode, it is configured as an output. When configured in input mode, CCLK is pulled up to VCC with an internal resistor

- **D0** Configuration Data Bus LSB (Input/Output)

D0 is used to transfer configuration data from or to the FPGA configuration SRAM. D0 is used for serial mode configuration.

- **INIT** (Input/Output)

INIT is used as an error indicator regarding configuration logic. INIT is a bidirectional open drain I/O pulled up to VCC with an internal resistor.

- **CON** Configuration Status Indicator (Input/Output)

CON is the FPGA configuration start and status pin. It is a bidirectional open drain I/O pulled up to VCC with an internal resistor.

- **HDC** High During Configuration (output)

HDC indicates that the configuration download is on-going. HDC is an output and is polarized to a high logic level during the configuration.

- **LDC** Low During Configuration (output)

LDC indicates that the configuration download is on-going. LDC is an output and is polarized to a low logic level during the configuration.

- **CS0\*** Configuration Chip Select (Input/Output)

CS0\* is an active low chip select used during configuration. It is only available configuration download slave serial mode 1

- **CSOUT** Configuration Cascade Output (Output)

CSOUT is the configuration pin used to enable the downstream device in an FPGA cascade chain.

- **CHECK\*** Configuration Check (Input/Output)

CHECK\* pin is used to enable the CHECK function when combined with a configuration download start.

- **OTS\*** Dual Use Tri State (Input)

OTS\* pin is used to tri-state all the FPGA pins configured as user I/Os.

## 1.2 Clock Interface

- **CLK** Processor reference clock (input)

This input provides a reference to generate the internal clock used by the processor and the internal peripherals.

- **BYPASS** Processor PLL bypass (input with pull-down)

This active high input is used to bypass the internal PLL. When asserted, the processor is directly clocked from the external reference clock. When de-asserted, the processor receives its clock from the internal PLL.

This signal shall be kept static and free from glitches while the processor is operating, as it is not sampled internally. Changing the signal shall only be performed while the processor is under reset otherwise the processor's behavior is not predictable.

- **LOCK** PLL lock (output)

When asserted, this active high output indicates the PLL of the processor is locked at a frequency corresponding to four times the frequency of the external processor reference clock.

Caution: this signal is de-asserted as soon as the PLL unlocks.

- **SKEW[1:0]** Clock tree skew (input with pull-down)

These input signals are used to programme the skew on the internal triplicated clock trees.

These signals shall be kept static and free from glitches while the processor is operating, as they are not sampled internally. Changing these signals shall only be performed while the processor is under reset otherwise the processor's behavior is not predictable.

- **GCK1 -GCK8** Global clock (input)

8 differential global clocks are available on the reconfigurable unit.

- **FCK3 – FCK4** Fast clock (input)

1 fast clock is available on the reconfigurable unit part. (The 2 pins are multiplexed all together).

## 1.3 Memory Interface

- **A[27:0]** Address bus (output)

The lower 28 bits of the 32 bit address bus carry instruction or data addresses during a fetch or a load/store operation to the external memory. The address of the last external memory access remains on the address bus whenever the current access can be made out of the internal cache.

- **D[31:0]** Data bus (bi-directional)

The 32-bit bi-directional data bus serves as the interface between the processor and the external memory. The data bus is only driven by the processor during the execution of integer & floating-point store instructions and the store cycle of atomic-load-store instructions. It is kept in high impedance otherwise. However: only D[31:24] are used during an access to an 8-bit area

D[15:0] are used as part of the general-purpose I/O interface whenever all the memory areas (ROM, SRAM & I/O) are 8-bit wide and the SDRAM interface is not enabled

- **CB[7:0]** Check bits (bi-directional)

These signals carry the EDAC checkbits<sup>1</sup> during a write access to the external memory and are kept in high impedance otherwise. This applies whatever the EDAC activation or not.

Note: 1. While only 7 bits are useful for EDAC protection, CB[7] is implemented to enable programming of FLASH memories and takes the value of MCFG3.tcb[7].

- **OE\*** Output enable (output)

This active low output is asserted during a read access to the external memory. It can be used as an output enable signal when accessing PROM & I/O devices.

- **READ** Read enable (output)

This active high output is asserted during a read access to the external memory. It can be used as a read enable signal when accessing PROM & I/O devices.

- **WRITE\*** Write enable (output)

This active low output is asserted during a write-access to the external memory. It can be used as a write enable signal when accessing PROM & I/O devices.

- **RWE\*[3:0]** PROM & SRAM byte write-enable (output)

These active low outputs provide individual write strobes for each byte-lane on the data bus: RWE\*[0] controls D[31:24], RWE\*[1] controls D[23:16], RWE\*[2] controls D[15:8] and RWE\*[3] controls D[7:0], and they are set according to the transaction width (word/half-word/byte) and the bus width set for the respective area.

- **BRDY\*** Bus ready (input)

When driven low, this input indicates to the processor that the current memory access can be terminated on the next rising clock edge. When driven high, this input indicates to the processor that it must wait and not end the current access.

### 1.3.1 PROM

- **ROMS\*[1:0]** PROM chip-select (output)

These active low outputs provide the chip-select signals for decoding the PROM area. ROMS\*[0] is asserted when the lower half of the PROM area is accessed (0x00000000 0x0FFFFFFF), while ROMS\* [1] is asserted when the upper half is accessed (0x10000000 0x1FFFFFFF).

### 1.3.2 SRAM

- **RAMS\*[4:0]** SRAM chip-select (output)

These active low outputs provide the chip-select signals for decoding five SRAM banks.

- **RAMOE\*[4:0]** SRAM output enable (output)

These active low signals provide an output enable signal for each SRAM bank.

### 1.3.3 I/O

- **IOS\*** I/O select (output)

This active low output provides the chip-select signal for decoding the memory mapped I/O area.

### 1.3.4 SDRAM

- **SDCLK** SDRAM clock (output)

This signal provides a reference clock for SDRAM memories. It is a copy of the processor internal clock.

- **SDCS\*[1:0]** SDRAM chip select (output)

These active low outputs provide the chip select signals for decoding two SDRAM banks.

- **SDRAS\*** SDRAM row address strobe (output)

This active low output provides the RAS signal (Row Access Strobe) for SDRAM devices.

- **SDCAS\*** SDRAM column address strobe (output)

This active low output provides the CAS signal (Column Access Strobe) for SDRAM devices.

- **SDWE\*** SDRAM write strobe (output)

This active low output provides the write strobe for SDRAM devices.

- **SDDQM[3:0]** SDRAM data mask (output)

These active high outputs provide the DQM strobe (Data Mask) for SDRAM devices.

## 1.4 Input / Output

- **GPIO[15:0]** – General Purpose Input Output (bi-directional)

These bi-directional signals can be used as general-purpose inputs or outputs to control external devices. Some of these signals have an alternate function and also serve as inputs or outputs for internal peripherals. Half of them are used as an internal mean of communication.

- **IOx** Programmable I/O (Input/Output)

The programmable IOs are dedicated to user's application. Each programmable IO can independently be configured as input, output or bidirectional IO.

## 1.5 LVDS Input Output

- **OLVDSx** LVDS Driver (Output)

OLVDSx where 'x' is the LVDS channel: A1, A2, B1 or B2

- **OLVDSxN** Complementary LVDS Driver (Output)

OLVDSxN where 'x' is the LVDS channel A1, A2, B1 or B2

- **ILVDSx** LVDS Receiver (Input)

ILVDSx where 'x' is the LVDS channel A1, A2, B1 or B2

- **ILVDSxN** Complementary LVDS Receiver (Input)

ILVDSxN where 'x' is the LVDS channel A1, A2, B1 or B2

- **LVDS\_REF\_A** reference voltage for LVDSA1 and LVDSA2 (1V25)

- **LVDS\_REF\_B** reference voltage for LVDSB1 and LVDSB2 (1V25)

## 1.6 DSU Interface

- **DSUEN** DSU enable (input)

When asserted, this synchronous active high input enables the DSU unit. If de-asserted, the DSU trace buffer will continue to operate but the processor will not enter debug mode.

This signal is meant for debug purpose and shall be driven low in the final application.

- **DSURX** DSU receiver (input)

This input provides the serial data stream to the DSU communication link receiver.

This signal is meant for debug purpose and shall be driven low in the final application.

- **DSUTX** DSU transmitter (output)

This output provides the serial data stream from the DSU communication link transmitter.

- **DSUACT** DSU active (output)

This active high output is asserted when the processor is in debug mode and controlled by the DSU.

- **DSUBRE** DSU break enable (input)

A low-to-high transition on this synchronous input signals a break condition and is used to set the processor into debug mode (see "Debug Support Unit" later in this document for specific use).

This signal is meant for debug purpose and shall be driven low in the final application.

## 1.7 Power Supply

- **PROC\_VCC33** I/O power (supply)

Power supply for the I/O pins of the processor.

- **FPGA\_VCC33** IO power (supply)

Power supply for the I/O pins of the reconfigurable unit.

- **PROC\_VDD18** Processor Core power (supply)

Power supply for the core of processor.

- **FPGA\_VDD18** FPGA Core power (supply)

Power supply for the core of reconfigurable unit.

- **VSS** I/O ground (supply)

Ground supply.

- **PROC\_VDD\_PLL** processor PLL power supply

Power supply for the PLL.

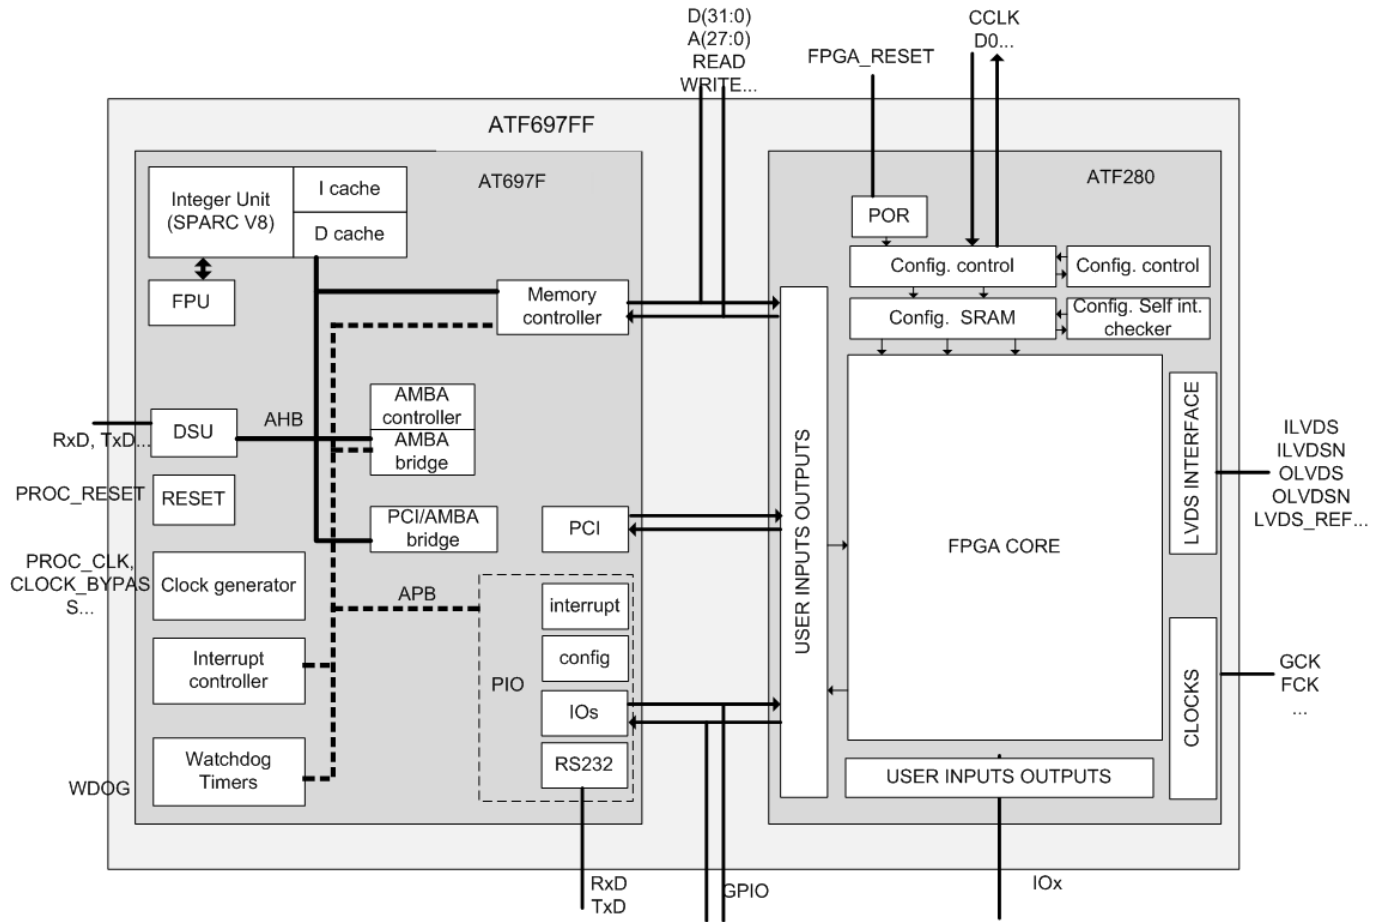

- **PROC\_VSS\_PLL** processor PLL ground supply

Ground supply for the PLL.

## 2. Architecture

ATF697FF is made of two separate units mounted on the same chip. The ATF697FF processor embeds an IU, and FPU and several peripherals including 2 32-bits timers, 1 watchdog, 16 GPIO, 2 UART interfaces, 1 PCI interface, an interrupt controller, a debug support unit controller and a flexible memory controller. The reconfigurable unit chip is made of a symmetrical array of identical cells, which are totally reconfigurable.

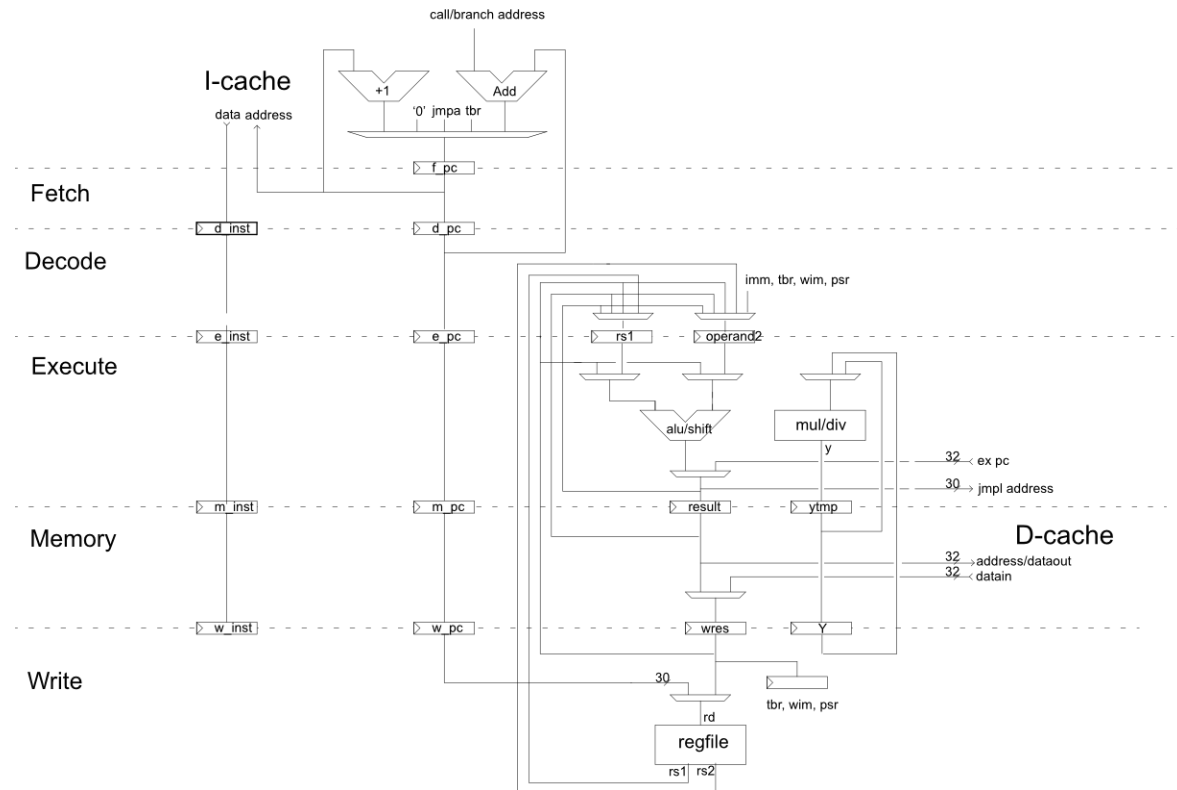

Figure 2-1. ATF697FF architecture overview

### 2.1 Integer Unit

The ATF697FF processor integer unit is based on the LEON2-FT architecture, it implements the SPARC integer instruction-set defined in the SPARC Architecture Manual version 8.

**Figure 2-2. Integer Unit Architecture**

To execute instructions at a rate approaching one instruction per clock cycle, the IU employs a five-stage instruction pipeline that permits parallel execution of multiple instructions.

- Fetch**  
 The instruction is fetched from the instruction cache is enabled and available or the fetch is forwarded to the memory controller.
- Decode**  
 The instruction is placed in the instruction register and decoded. The operands are read from the register file and/or from immediate data and the next instruction computed CALL/Bicc target addresses are generated.
- Execute**  
 Arithmetic, logical and shift operations are performed and the result saved in temporary registers. Memory and JMPL/RETT target address are generated. Pending traps are prioritized and internal traps are taken, if any.
- Memory**  
 On a memory load instruction, data is read from the data cache if enabled and available or the read is forwarded to the memory controller. On a memory store instruction, store data is always forwarded to the memory controller and any matching data cache entry is invalidated if enabled.
- Write**  
 The result of any arithmetic, logical, shift or memory/cache read operation is written back to the register file.

All five stages operate in parallel, working on up to five different instructions at a time.

A basic "single-cycle" instruction enters the pipeline and completes in five cycles. By the time it reaches the write stage, four more instructions have entered and are moving through the pipeline behind it. So, after the first five cycles, a single-cycle instruction exits the pipeline and a single-cycle instruction enters the pipeline on every cycle.

Of course, a "single-cycle" instruction actually takes five cycles to complete, but they are called single cycle because with this type of instruction the processor can complete one instruction per cycle after the initial five-cycle delay.

**Table 2-1. Cycles per instruction (assuming cache hit and no load interlock)**

Instruction	Cycles
Jump and Link (JMPL)	2
Load Double-Word (LDD)	2
Store Single-Word (ST)	2
Store Double-Word (STD)	3
Integer Multiply (SMUL/UMUL/SMULcc/UMULcc)	5
Integer Divide (SDIV/UDIV/SDIVcc/UDIVcc)	35
Taken Trap (Ticc)	4
Atomic Load/Store (LDSTUB)	3
All other IU instructions	1
Single-Precision Multiply (FMULS)	16 <sup>1</sup>
Double-Precision Multiply (FMULD)	21 <sup>1</sup>
Single-Precision Divide (FDIVS)	20 <sup>1</sup>
Double-Precision Divide (FDIVD)	36 <sup>1</sup>
Single-Precision Square-Root (FSQRTS)	37 <sup>1</sup>
Double-Precision Square-Root (FSQRTD)	65 <sup>1</sup>
Single-Precision Absolute Value (FABS)	2 <sup>1</sup>
Single-Precision Move (FMOVS)	2 <sup>1</sup>
Single-Precision Negate (FNEGS)	2 <sup>1</sup>
Convert Single to Double-Precision (FSTOD)	2 <sup>1</sup>
All other arithmetic FPU instructions	7 <sup>1</sup>

Note: 1. This value is to be considered "typical". As the execution of FPU operations is operand-dependent, the true execution time can be lower or higher than mentioned.

### 2.1.1 Program Counters

The Program Counter (PC) contains the address of the instruction currently being executed by the Integer Unit, and the next Program Counter (nPC) holds the address (PC + 4) of the next instruction to be executed (assuming there is no control transfer and a trap does not occur). The nPC is necessary to implement delayed control transfers, wherein the instruction that immediately follows a control transfer may be executed before control is transferred to the target address.

Having both the PC and nPC available to the trap handler allows a trap handler to choose between retrying the instruction causing the trap (after the trap condition has been eliminated) or resuming program execution after the trap causing instruction.

## 2.1.2 Windowed Register File

The ATF697FF processor contains a 136×32 register file divided into 8 overlapping windows, each window providing a working registers set at a time. Working registers are used for normal operations and are called r registers.

The 136 registers are 32-bits wide and are divided into a set of 8 global registers and a set of 128 window registers grouped into 8 sets of 24 r registers called windows. At any given time, a program can access 32 active r registers (r0 to r31): 8 (common) global registers (r0 to r7) and 24 window registers (r8 to r31) that are divided by software convention into 8 ins, 8 locals and 8 outs:

- The first 8 globals (r0 to r7) are also called g registers (g0 to g7), they usually hold common data to all functions (as a special case, r0/g0 always returns the value 0 when read and discards the value written to it)
- The next 8 ins (r8 to r15) are also called i registers (i0 to i7), they usually are the input parameters of a function
- The next 8 locals (r16 to r23) are also called l registers (l0 to l7), they usually are scratch registers that can be used for anything within a function
- The last 8 outs (r24 to r31) are also called o registers (o0 to o7), they usually are the return parameters of a function

The register file can be viewed as a circular stack, with the highest window joined to the lowest. Note that each window shares its ins and outs with adjacent windows: outs from a previous window are the ins of the current window and the outs of the current window are the ins of the next window.

Figure 2-3. Circular Stack of Overlapping Windows

The register file implementation is based on two dual-port RAMs. The first dual-port RAM provides the first operand of a SPARC instruction while the second dual-port RAM provides the second operand unless an immediate value is needed. When applicable, the result of the instruction is written back into the register file, so the two dual-port RAMs always have equal contents.

When one function calls another, the calling function can choose to execute a SAVE instruction. This instruction decrements an internal counter, the current window pointer (CWP), shifting the register window downward. The caller's out registers then become the calling function's in registers and the calling function gets a new set of local and out registers for its own use. Only the pointer changes because the registers and return address do not need to be stored on a stack. The RESTORE/RETT instructions acts in the opposite way

The Window Invalid Mask register (WIM) is controlled by supervisor software and is used by the hardware to determine whether a window overflow or underflow trap is to be generated by a SAVE, RESTORE or RETT instruction.

When a SAVE, RESTORE or RETT instruction is executed, the current value of the CWP is compared against the WIM register. If the SAVE, RESTORE, or RETT instruction would cause the CWP to point to an “invalid” register set, a window\_overflow or window\_underflow trap is caused.

### 2.1.3 Arithmetic & Logic Unit

The high-performance ALU operates in direct connection with all the 32 working registers. Within a single clock cycle, a 32-bit arithmetic operation between two working registers or between a working register and an immediate value is executed.

#### 2.1.3.1 State Register

The Processor State Register (PSR) contains fields that report the status of the processor operations or control processor operations.

Instructions that modify its fields include SAVE, RESTORE, Ticc, RETT and any instruction that modifies the condition code fields (icc). Any hardware or software action that generates a trap will also modify some of its fields.

A global interrupt management is provided: traps and interrupts (asynchronous traps) can be enabled/disabled and interrupts level response can be fine tuned.

#### 2.1.3.2 Instruction Set

ATF697FF processor SPARC instructions fall into six functional categories: load/store, arithmetic/logical/ shift, control transfer, read/write control register, floating-point and miscellaneous. Please refer to the SPARC V8 Architecture Manual for further details.

#### 2.1.3.3 Multiply instructions

The ATF697FF processor fully supports the SPARC V8 multiply instructions (UMUL, SMUL, UMULcc and SMULcc). The multiply instructions perform a 32x32-bit integer multiply producing a 64-bit result. SMUL and SMULcc perform signed multiply while UMUL and UMULcc performs unsigned multiply. UMULcc and SMULcc also set the condition codes to reflect the result. The Y register holds the most-significant half of the 64-bit result.

#### 2.1.3.4 Divide Instructions

The ATF697FF processor fully supports the SPARC V8 divide instructions (UDIV, SDIV, UDIVcc and SDIVcc). The divide instructions perform a 64x32 bit divide and produce a 32-bit result. SDIV and SDIVcc perform signed multiply while UDIV and UDIVcc performs unsigned divide. UDIVcc and SDIVcc also set the condition codes to reflect the result. Rounding and overflow detection is performed as defined in the SPARC V8 standard. The Y register holds the most-significant half of the 64-bit divided value.

## 2.2 Floating-Point Unit

The ATF697FF processor floating-point unit is based on the MEIKO core and implements the SPARC floating-point instruction-set defined in the SPARC Architecture Manual version 8.

The FPU interface is integrated into the IU pipeline and does not implement a floating-point queue<sup>1</sup>, so the IU is stopped during the execution of floating-point instructions.

Note: 1. This means the qne bit in the FSR register is always zero and any attempts to execute the STDFQ instruction will generate an FPU\_exception trap (0x08).

The ATF697FF processor contains a 32x32 register file for floating-point operations, referred to as f registers (f0 to f31). These registers are 32-bits wide and can be concatenated to support 64-bits double-words (extended precision instructions and format are not supported). The whole 32 registers set is available at all time for any floating-point operation.

Integer and single-precision data require a single 32-bit f register. Double-precision data require 64-bit of storage and occupy an even-odd pair of adjacent registers.

## 2.3 Memory Mapping

The 32-bit addressable memory space is divided into 6 areas, each area being allocated to a specific device type and externally or internally decoded accordingly:

**Table 2-2. Memory Mapping**

Address Range	Area	Device Select Signals
0x00000000 0x1FFFFFFF	PROM <sup>1 2</sup>	2
0x20000000 0x3FFFFFFF	I/O <sup>1</sup>	1
0x40000000 0x7FFFFFFF	RAM <sup>2</sup>	5 (SRAM) + 2 (SDRAM)
0x80000000 0x8FFFFFFF	REGISTER <sup>1</sup>	n/a (internal)
0x90000000 0x9FFFFFFF	DSU <sup>1</sup>	
0xA0000000 0xFFFFFFFF	PCI <sup>1</sup>	see PCI/cPCI specification

Note: 1. Area is equally accessible in User & Supervisor mode on read & write access

Note: 2. Write protection may apply if enabled on the area

## 2.4 Fault Tolerance

The processor has been especially designed for radiation-hardened applications. To prevent erroneous operations from single event transient (SET) and single event upset (SEU) errors, the ATF697FF processor implements a set of protection features including:

- Full triple modular redundancy (TMR) architecture
- Programmable skews on the clock trees
- EDAC protection on IU and FPU register files
- EDAC protection on external memory interface
- Parity protection on instruction and data caches

### 2.4.1 Triple Modular Redundancy

To protect against SEU errors (Single Event Upset), each on-chip register is implemented using triple modular redundancy (TMR). This means that any SEU register error is automatically removed within one clock cycle while the output of the register maintains the correct (glitch-free) value.

Moreover, an independent clock tree is used for each of the three registers making up one TMR module. This feature protects against SET errors (Single Event Transient) in the clock tree, to the expense of increased routing.

The CPU clock and the PCI clock are built as three-clock trees. The same triplication is applied to the CPU reset and to the PCI reset as well.

Figure 2-4. TMR Register with Separate Clock-Tree

#### 2.4.2 Clock-Tree Skew

Optionally, a skew can be applied between each of the three branches of the clock trees in order to provide additional SET protection.

#### 2.4.3 Register File SEU Protection

To prevent erroneous operations from SEU errors in the IU and FPU register file, each register is protected using a 7-bit EDAC checksum. Checking of the EDAC bits is done every time a fetched register value is used in an instruction. If a correctable error is detected, the erroneous data is corrected before being used. At the same time, the corrected register value is also written back to the register file. A correction operation incurs a delay 4 clock cycles, but has no other software visible impact. If an uncorrectable error is detected, a `register_hardware_error` trap (0x20) is generated.

#### 2.4.4 Cache Parity

The cache parity mechanism is transparent to the user, but in case of a cache parity error, a cache miss is generated and an access to external memory is performed to reload the cache entry, implying some delay.

## 2.5 Operating Modes

### 2.5.1 Reset Mode

The processor asynchronously enters reset mode as soon as the PROC\_RESET\* signal is asserted. It synchronously exits reset mode on the 5th rising edge of the SDCLK signal after the PROC\_RESET\* signal has been deasserted.

While in reset mode, the IU, the FPU and all the peripherals are halted. The processor disables traps (PSR.et = 0), sets the supervisor mode (PSR.s = 1) and sets the program counter to location zero (PC = 0 & nPC = 4). Other IU, FPU and peripheral registers are initialized as well (see "Register Description").

On exit from reset mode, the processor enters execute mode.

### 2.5.2 Execute Mode

In execute mode, the processor fetches instructions and executes them in the IU (Integer Unit) or the FPU (Floating-Point Unit). Please refer to "The SPARC Architecture Manual Version 8" for further information.

### 2.5.3 Error Mode

The processor enters error mode when a synchronous trap must occur while traps are disabled (PSR.et = 0).

This essentially means that a trap which cannot be ignored occurred while another trap is being serviced. In order for that synchronous trap to be serviced, the processor goes through the normal operation of a trap, including setting the trap-type bits (TBR.tt) to identify the trap type. It then enters error mode, halts and asserts the ERROR\* signal.

The only way to leave error mode is to assert the PROC\_RESET\* signal, which forces the processor into reset mode. All information placed in the IU, FPU and all peripherals registers from the last execute mode (the trap operation) remains unchanged unless stated otherwise (see "Register Description"). The code executed upon exit from reset mode can examine the trap type of the synchronous trap and the IU, FPU and all peripherals registers and deal with the information they contain accordingly.

### 2.5.4 Idle Mode

While in execute mode, the processor may enter idle mode in software.

Entry into idle mode is initiated by writing any value to the idle register (IDLE) and made effective on the next load instruction (caution). While in idle mode, the IU stops fetching instructions and is kept into a minimal activity. All other peripherals operate as nominal.

**Caution:** In order to avoid any unwanted side-effect (idle entry not on the foreseen load instruction), the load instruction shall immediately follow the write operation to the idle register,

Idle mode is terminated as soon as an unmasked interrupt is pending (ITP.ipend) with an interrupt number of 15 or greater than the current processor interrupt level (PSR.pil). Then the processor directly goes through the normal operation of servicing the interrupt.

### 2.5.5 Debug Mode

**Caution:** This section is for information purpose only.

**Caution:** As its name clearly states, the Debug Support Unit (DSU) is exclusively meant for debugging purpose. None of the DSU features shall ever be used in the final application where the DSU shall be turned into an inactive state (DSUEN, DSUBRE and DSURX tied to a permanent low level).

As a special case when the DSU is enabled (DSUEN signal asserted), debug mode is entered when specific conditions are met (see "Debug Support Unit" and "Register Description" chapters later in this document).

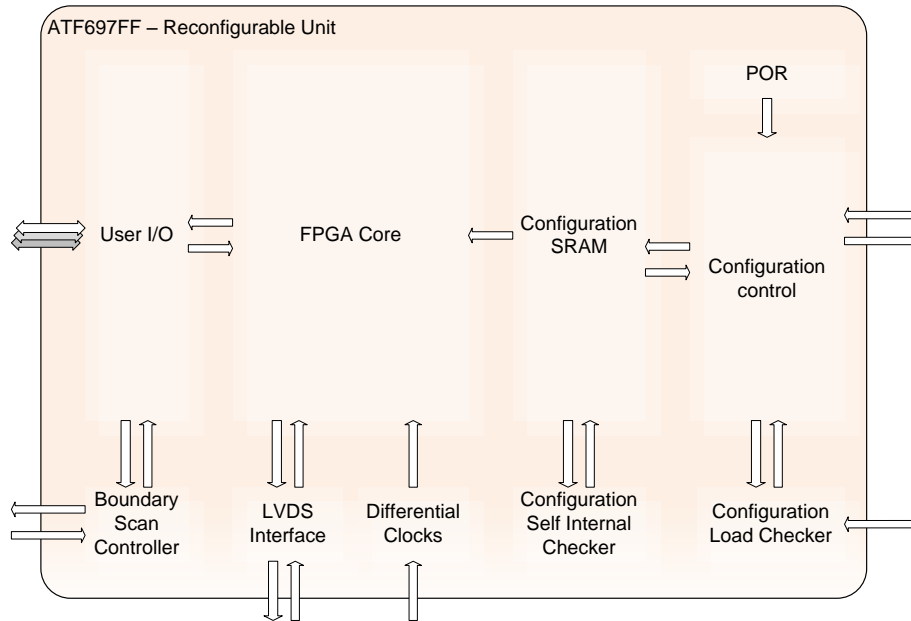

In debug mode, the processor pipeline is held and the processor is controlled by the DSU so all processor registers, caches memories and even external peripherals can be accessed.

## 2.6 Architecture of the reconfigurable unit

The ATF697FF reconfigurable unit architecture is developed to provide the highest levels of performance, functional density and design flexibility in an FPGA. The cells in the Atmel array are small, efficient and can implement any pair of Boolean functions of (the same) three inputs or any single Boolean function of four inputs. The cell's small size leads to arrays with large numbers of cells, greatly multiplying the functionality in each cell. A simple, high-speed busing network provides fast, efficient communication over medium and long distances.

Here is an overview of the internal architecture of the ATF697FF reconfigurable unit:

**Figure 2-5. ATF697FF reconfigurable unit Architecture Overview**

### 2.6.1 FPGA Core

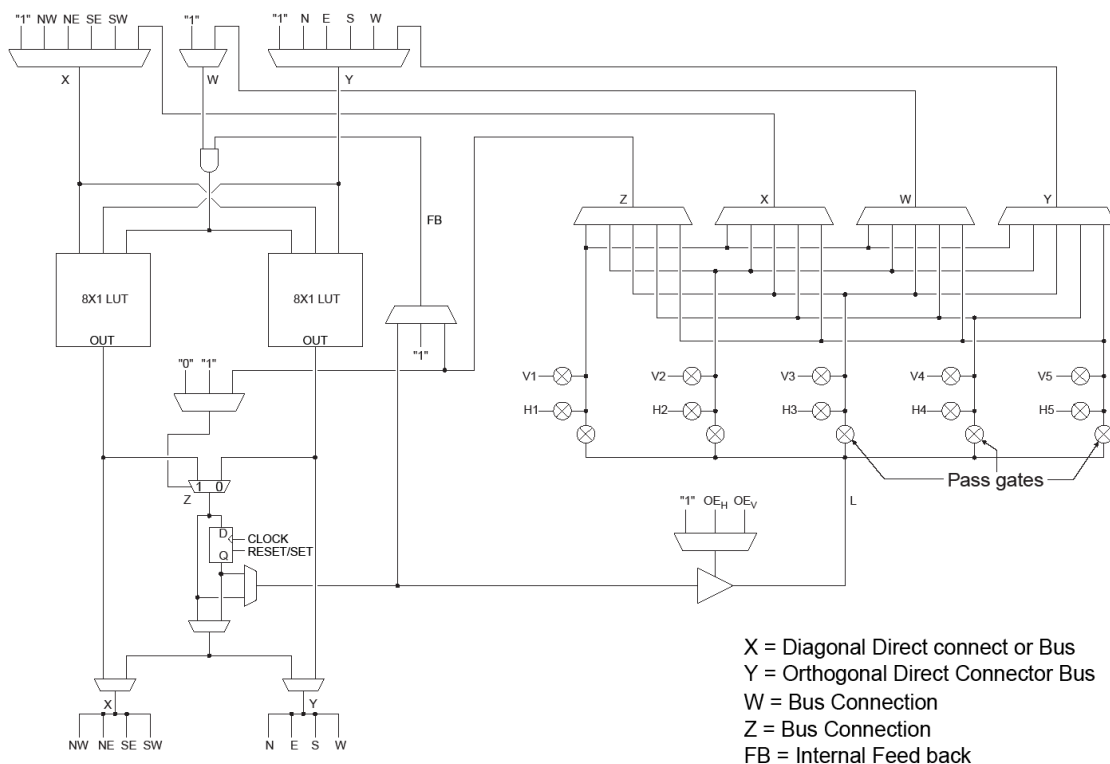

At the heart of the Atmel reconfigurable unit architecture is a symmetrical array of identical cells. The array is continuous from one edge to the other, except for bus repeaters spaced every four cells. At the intersection of each repeater row and column is a 32 x 4 RAM block accessible by adjacent buses.

**Figure 2-6. Core device overview**

The following figure depicts the reconfigurable unit cell which is a highly configurable logic block based around two 3-input LUTs (8 x 1 ROM), and which can be combined to produce one 4-input LUT. This means that any cell can implement two functions of 3 inputs or one function of 4 inputs.

**Figure 2-7. ATF697FF reconfigurable unit Core Cell**

Every cell includes a register element, a D-type flip-flop, with programmable clock and reset polarities. The initialization of the register is also programmable. It can be either SET or RESET. The flip-flop can be used to register the output of one of the LUT. It can also be exploited in conjunction with the feedback path element to implement a complete ripple counter stage in a single cell. The registered or unregistered output of each LUT can be feedback within the cell and treated as another input. This allows, for example, a single counter stage to be implemented within one cell without using external routing resources for the feedback connection.

There is also a 2-to-1 multiplexer in every cell, and an upstream AND gate in the “front end” of the cell. This AND gate is an important feature in the implementation of efficient array multipliers as the product and carry terms can both be generated within a single logic cell.

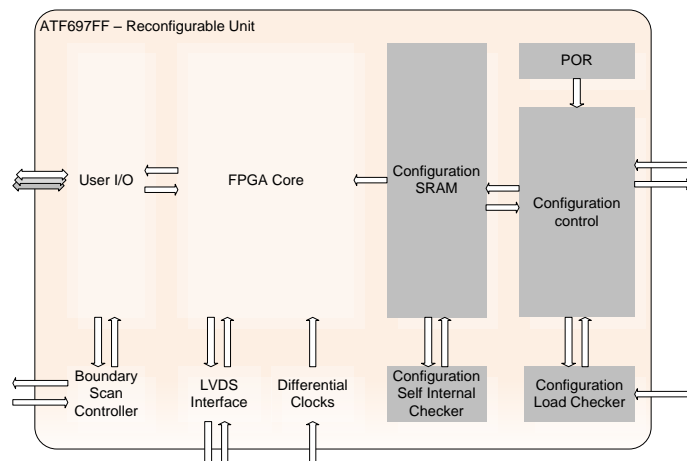

The cell flexibility makes the ATF697FF reconfigurable unit architecture well suited for most of the digital design application areas.

## 2.6.2 Configuration Logic

The ATF697FF reconfigurable unit embeds the configuration logic function which is responsible of the configuration download. The configuration download is the operation by which the FPGA configuration SRAM is written in order to load the FPGA application. The configuration download operation is fully detailed in **Configuration Download** section of this document.

The configuration logic is based on the 5 modules highlighted in the following figure.

**Figure 2-8. Configuration Logic Highlight**

### 2.6.2.2 POR

The POR module is an analogic structure which senses the rise of the FPGA\_VDD18 Power Supply. While FPGA\_VDD18 is under the POR threshold, all the FPGA logic is maintained in a reset state. Once, the FPGA\_VDD18 rises above the POR threshold, all the FPGA logic is activated (leaves reset state) and the FPGA enters in **Power-On Reset** lifephase.

### 2.6.2.3 Configuration Control

The Configuration Control module is the main module of the configuration logic. It interfaces directly the POR module in order to manage the **Power-On Reset** lifephase. It also manages the configuration SRAM module and is capable to access SRAM cells in read or write mode. It drives the external configuration interface signals used to manage the configuration download. To finish, the configuration control is interconnected with the Configuration Load Checker module to ensure the integrity of the communication protocol.

### 2.6.2.4 Configuration SRAM

The configuration SRAM module is made of a large set of SRAM memory points distributed through the whole FPGA. The configuration SRAM is fully cleared during the **Power-On Reset** and **Manual Reset** lifephases. It is written during **Configuration Download** lifephase with the bitstream data in order to configure the FPGA matrix. The configuration SRAM can also be read for integrity verification when using special function such as CHECK function or CSIC function. Refer to **Configuration Integrity Management** section for detailed description of those functions.

### 2.6.2.5 Configuration Load Checker

The Configuration Load Checker module is responsible of the protection of the configuration download link. During the **Configuration Download** lifephase it manages the errors which are protocol relevant and informs the configuration control module of any error in such a way that the configuration control module can drive the appropriate error status signals to inform the system that an error occurred during the configuration.

### 2.6.2.6 Configuration Self Internal Checker

The Configuration Self Internal Checker module is responsible of the integrity of the data during the **Run** lifephase. Once the configuration SRAM is written with the appropriate data, the ATF697FF reconfigurable unit is capable to check all its effective configuration data and to notify the user in case of errors inside the configuration SRAM. This mechanism is useful to detect SEU that occur on the configuration SRAM.

### **2.6.3 User I/O**

The ATF697FF reconfigurable unit features up to 150 general purpose IO for end user application. Each IO can be individually adjusted to the application needs thanks to its extensive configurability. All the IOs are cold sparing, have PCI compliance capability...

Please refer to the General Purpose Interface section for detailed information on the User IOs.

### **2.6.4 LVDS I/O**

The ATF697FF reconfigurable unit provides a 200MHz LVDS interface with cold sparing feature. This interface can be used for high speed communication between the FPGA and its peripherals in order to exchange large amount of data.

Please refer to the LVDS Interface section for detailed information on the LVDS IOs

### **2.6.5 Clock**

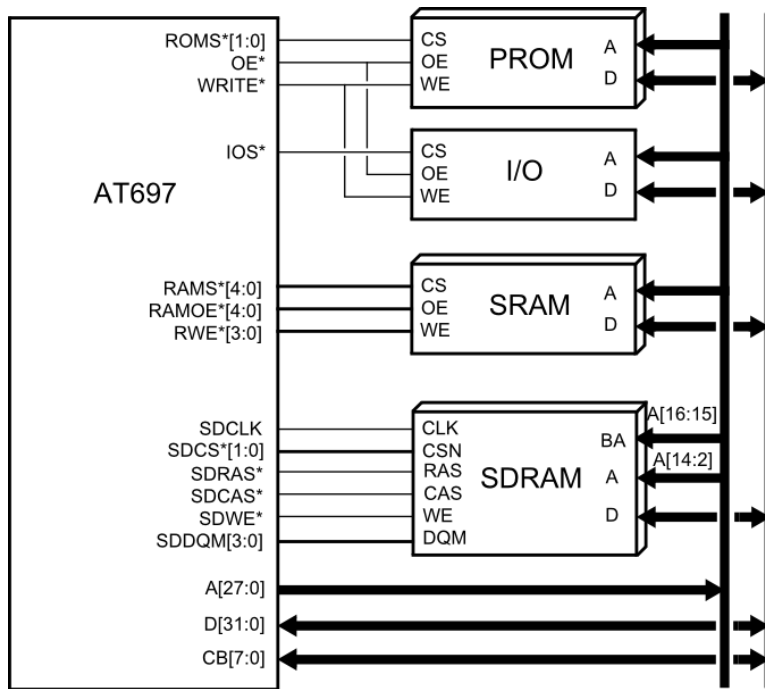

Please refer to the Clock section for detailed information on clock system implemented on the ATF697FF reconfigurable unit.

### 3. Flexible memory interface

#### 3.1 Overview

The ATF697FF processor provides a direct memory interface to PROM, memory mapped I/O, asynchronous static ram (SRAM) and synchronous dynamic ram (SDRAM) devices.

Figure 3-1. Memory Interface Overview<sup>1</sup>

Note: 1. WRITE\* and RWE\* [3:0] present redundant information and they can be used in PROM and SRAM areas. The memory controller decodes a 2 GB address space and performs chip-select decoding for two PROM banks, one I/O bank, five SRAM banks and two SDRAM banks.

Table 3-1. Memory Controller Address Map

Address Range	Size	Area
0x00000000 0x1FFFFFFF	512M	PROM
0x20000000 0x3FFFFFFF	512M	I/O
0x40000000 0x7FFFFFFF	1G	SRAM and/or SDRAM

The memory data bus width can be configured for either 8-bit or 32-bit access, independently for PROM, memory-mapped I/O and SRAM. A fixed 32-bit wide data bus is required for SDRAM.

EDAC protection is available for PROM, SRAM and SDRAM memories (CB[7:0] are always driven on a write access in 32-bit mode even when EDAC is not activated).

To improve the bandwidth of the memory bus, accesses to consecutive addresses can be performed in burst mode. Burst transfers will be generated when the memory controller is accessed using a burst request from the internal bus. These includes instruction cache-line fills, double-word loads and double-word stores.

The memory interface is controlled through 3 memory configuration registers:

- MCFG1 is dedicated to PROM and I/O configuration
- MCFG2 & MCFG3 are dedicated to SRAM and SDRAM configuration

## 3.2 PROM Interface

### 3.2.1 Overview

The memory controller allows addressing of up to 512 MB of PROM in two banks. PROM memory access control is performed using dedicated chip selects (ROMS\* [1:0]) and common output enable (OE\*), read (READ) and write (WRITE\*) signals.

PROM banks map as follows:

- ROMS\* [0] decodes the 256 MB lower half of the PROM area (0x00000000 0x0FFFFFFF)
- ROMS\* [1] decodes the 256 MB upper half of the PROM area (0x10000000 0x1FFFFFFF)

The PROM interface is controlled in the memory configuration registers (MCFG1 and MCFG3):

- data bus width<sup>1</sup> can be 8-bit or 32-bit (MCFG1.prwdh)
- wait-states<sup>2</sup> can be programmed for read access (MCFG1.prrws) and write access (MCFG1.prwws)
- write can be enabled/disabled (MCFG1.prwen)
- EDAC protection<sup>3</sup> can be enabled/disabled (MCFG3.pe)
- read/write access can be BRDY\* -controlled (MCFG1.pbrdy) synchronously/asynchronously<sup>4</sup> (MCFG1.abrdy)

Note: 1. Upon reset, the PROM data bus width is automatically configured from the value read on the GPIO[1:0] pins. By driving GPIO[1:0] appropriately during reset, it is possible to set the PROM data bus width on boot.

Note: 2. Upon reset, the PROM wait-states are set to the maximum value to allow booting on even the slowest memory.

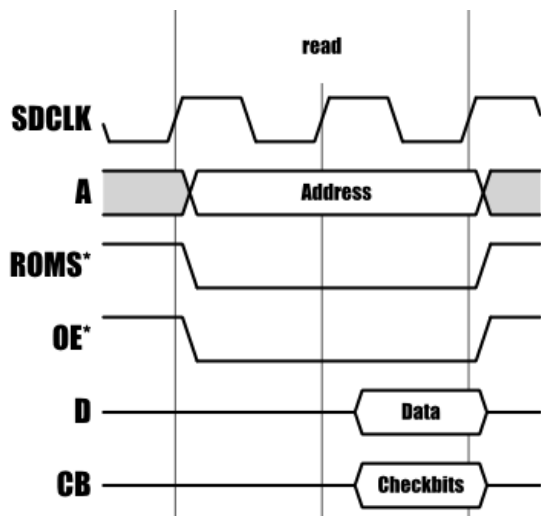

Note: 3. Upon reset, the PROM EDAC protection is automatically configured from the value read on the GPIO[2] pin.

Note: 4. Asynchronous BRDY\* -control feature common to PROM, SRAM and I/O interfaces.

### 3.2.2 Read Access

A PROM read access consists in two data cycles.

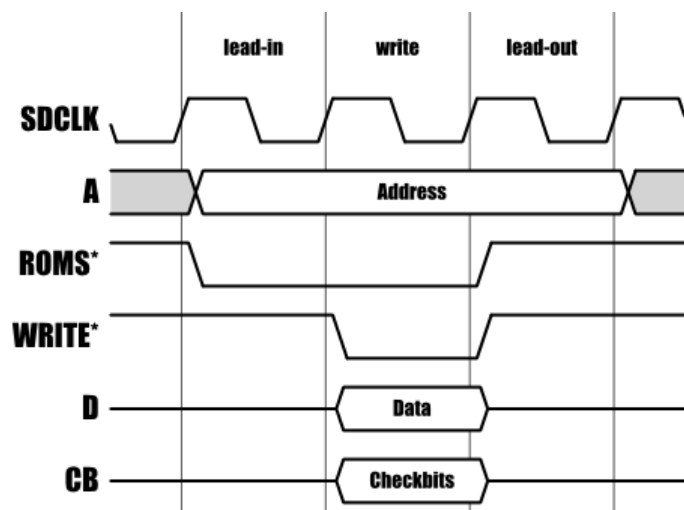

Figure 3-2. PROM Read Access (no wait-states)

### 3.2.3 Write Access

A PROM write access consists in an address lead-in cycle, a data write cycle and an address lead-out cycle. The write operation is strobed by the WRITE\* signal.

Figure 3-3. PROM Write Access (no wait-states)

### 3.2.4 Wait-States

For application accessing slow PROM memories, the memory controller allows to insert wait-states during a PROM read access (MCFG1.prrws) and write access (MCFG1.prwsws). Up to 30 wait-states can be inserted in steps of 2 (number of wait-states is twice the programmed value).

Figure 3-4. PROM Read Access with 2 Wait-States (MCFG1.prrws=1)

PROM read/write access can further be stretched when even more delay is needed (see "BRDY\* -Controlled Access" later in this chapter").

### 3.2.5 Write Protection

PROM write access is disabled after reset and shall be enabled (MCFG1.prwen = 1) before any write access is attempted. Otherwise the write access is cancelled and a write\_error trap (0x2B) is taken.

#### Data Bus Width

When configured for 32-bit PROM (MCFG1.prwdh = 00), D[31:0] shall be connected to the memory device(s). CB[7:0] shall be connected as well if EDAC protection is activated (MCFG3.pe = 1).

To support applications with limited memory and/or limited performance requirements, the PROM area can be configured for 8-bit operations.

When configured for 8-bit PROM (MCFG1.prwdh = 00), D[31:24] shall be connected to the memory device(s).

Figure 3-5. 8-bit PROM Interface

Since an IU load operation is always performed on a word basis (32-bit), read access to 8-bit memory is transformed into a burst of 4 read access to retrieve the 4 bytes. If EDAC protection is activated, a 5th byte read access is performed as well to retrieve the checkbits (see "Error Management EDAC" section later in this chapter).

During a store operation, only the necessary bytes are written if EDAC protection is not activated.

**Caution:** When EDAC protection is activated, only a full word write operation shall be performed (5 bytes).

## 3.3 Memory-Mapped I/O

### 3.3.1 Overview

The memory controller allows addressing a single memory-mapped I/O area. I/O memory access control is performed using a dedicated chip select ( $IOS^*$ ) and common output enable ( $OE^*$ ), read (READ) and write ( $WRITE^*$ ) signals. No EDAC protection is available in this area.

$IOS^*$  decodes a fixed 512 MB<sup>1</sup> area (0x20000000 0x3FFFFFFF).

The I/O interface is controlled in the memory configuration registers (MCFG1):

- interface can be enabled/disabled (MCFG1.ioen)
- data bus width can be 8-bit or 32-bit (MCFG1.iowdh)<sup>2</sup>
- wait-states can be programmed for read and write access (MCFG1.iows)
- read/write access can be  $BRDY^*$ -controlled (MCFG1.iobrdy) synchronously/asynchronously<sup>3</sup> (MCFG1.abrdy)

Note: 1. The upper 256 MB area (0x30000000 0x3FFFFFFF) is a shadow of the lower 256 MB area (0x20000000 0x2FFFFFFF) because of the 28 bits address bus limitation.

Note: 2. The I/O area shall only be accessed with load/store instructions of a size matching the configured bus width (LDUB/LDSB/STB when in 8-bit mode and LD/ST when in 32-bit mode).

Note: 3. Asynchronous  $BRDY^*$ -control feature common to PROM, SRAM and I/O interfaces.

### 3.3.2 Interface Enable

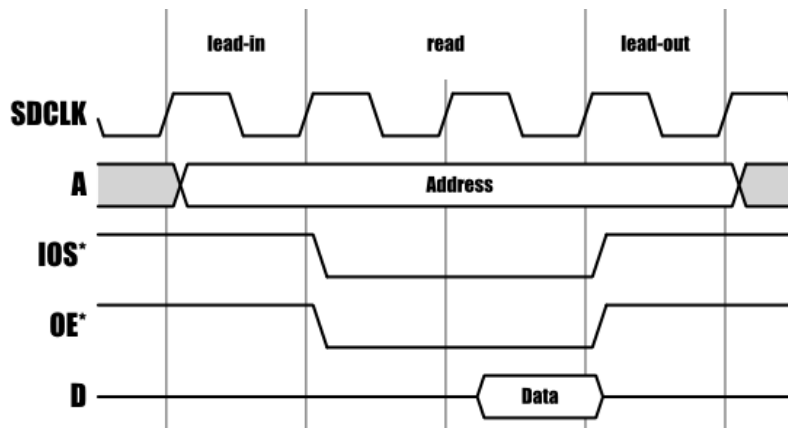

The I/O interface shall be enabled (MCFG1.ioen) before any read or write access is attempted, otherwise the access is cancelled and:

- an instruction\_access\_exception trap (0x01) is generated if an instruction fetch is in progress
- a data\_access\_exception trap (0x09) is generated if a data load is in progress
- a write\_error trap (0x2B) is generated if a data store is in progress

### 3.3.3 Read Access

An I/O read access consists in a address lead-in cycle (the  $IOS^*$  signal is delayed by one clock cycle to provide a stable address for sampling), two data cycles and an address lead-out cycle.

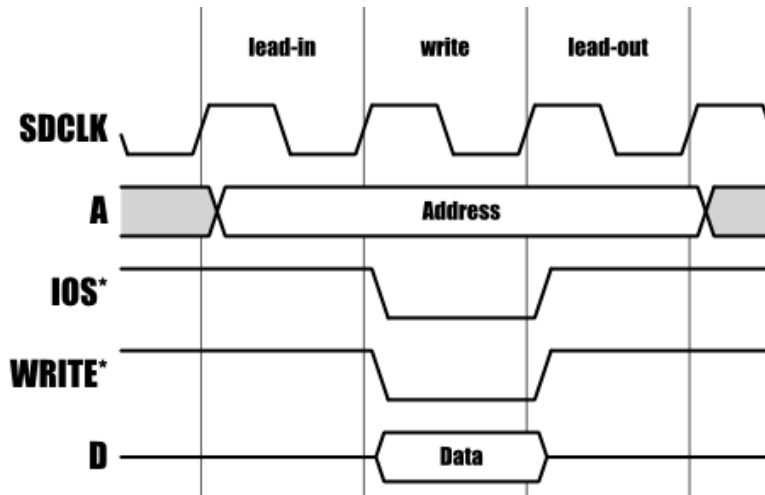

Figure 3-6. I/O Read Access (no wait-states)

### 3.3.4 Write Access

An I/O write access consists in an address lead-in cycle, a data write cycle and an address lead-out cycle. The write operation is strobed by the WRITE\* signal.

Figure 3-7. I/O Write Access (no wait-states)

### 3.3.5 Wait-States

For application accessing slow I/O devices, the memory controller allows to insert wait-states during an I/O read /write access (MCFG1.iows). Up to 15 wait-states can be inserted.

An I/O read/write access can further be stretched when even more delay is needed (see "BRDY\* -Controlled Access" later in this chapter").

### 3.3.6 Data Bus Width

When configured for 32-bit I/O (MCFG1.iowdh = 00), D[31:0] shall be connected to the I/O device(s). Only 32-bit load/store instructions (LD, ST) shall be used then.

When configured for 8-bit I/O (MCFG1.iowdh = 01), D[31:24] shall be connected to the I/O device(s). Only 8-bit load/store instructions (LDUB, LDSB, STB) shall be used then.

Figure 3-8. 8-bit I/O interface

## 3.4 RAM Interface

The memory controller allows to control up to 1 GB of RAM. The global RAM area supports two RAM types: asynchronous static RAM (SRAM) and synchronous dynamic RAM (SDRAM).

## 3.4.1 SRAM Interface

### 3.4.1.1 Overview

The memory controller allows addressing of up to 768 MB of SRAM in 5 banks. SRAM memory access control is performed using dedicated chip selects (RAMS\* [4:0]), output enables (RAMOE\* [3:0]) and byte-write enables (RWE\* [3:0]) signals.

SRAM banks map as follows:

- RAMS\* [0], RAMS\* [1], RAMS\* [2] and RAMS\* [3] decode contiguous banks with a common programmable size (8 KB to 256 MB) at the lower half of the RAM area (from 0x40000000 onwards)
- RAMS\* [4] decodes a fixed 256 MB at the upper half of the RAM area (0x60000000 0x6FFFFFFF) unless the SDRAM interface is enabled

The SRAM interface is controlled in the memory configuration registers (MCFG2 and MCFG3):

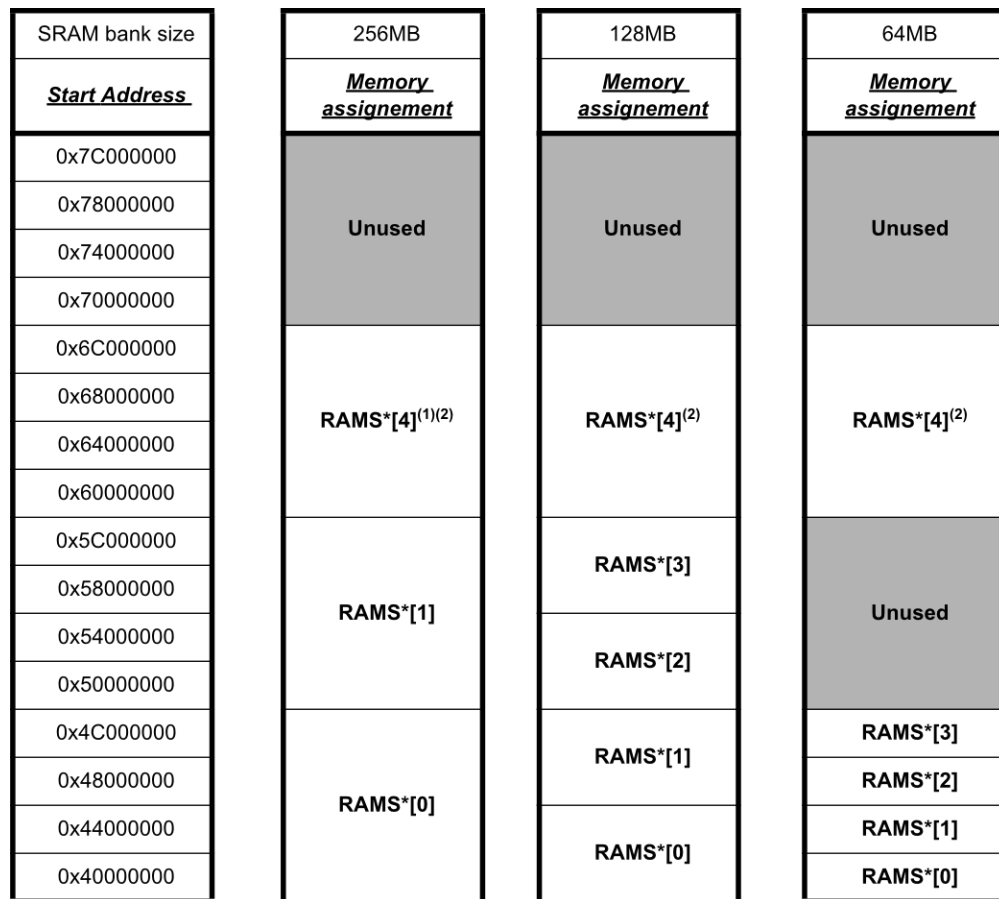

- interface can be enabled/disabled (MCFG2.si)
- data bus width can be 8-bit or 32-bit (MCFG2.ramwdh)
- bank size can be set from 8 KB to 256 MB (MCFG2.rambs)
- wait-states can be programmed for read access (MCFG2.ramrws) and write access (MCFG2.ramwws)
- read-modify-write can be activated for sub-word write operations (MCFG2.ramrmw)
- EDAC protection<sup>1</sup> can be enabled/disabled (MCFG3.re)
- read/write access can be BRDY\* -controlled (MCFG2.rambrdy) synchronously/asynchronously<sup>2</sup>. (MCFG1.abrdy)

Note: 1. EDAC protection activation common to SRAM and SDRAM interfaces.

Note: 2. Asynchronous BRDY\* -control feature common to PROM, SRAM and I/O interfaces.

Figure 3-9. SRAM Bank Organization

Note: 1. When SRAM bank size is set to 256 MB, bank 2 and bank 3 overlap with bank 4. Because priority is given to bank 4, bank 2 and bank 3 control signals are never asserted.

Note: 2. When SDRAM is enabled, priority is given to the SDRAM over the SRAM. Any memory access above 0x60000000 is assigned to SDRAM and no SRAM control signal is asserted.

### 3.4.1.2 Read Access

An SRAM read access consists in two data cycles. A dedicated output enable signal is provided for each SRAM bank (RAMOE\* [i]) and is only asserted when that bank is selected.

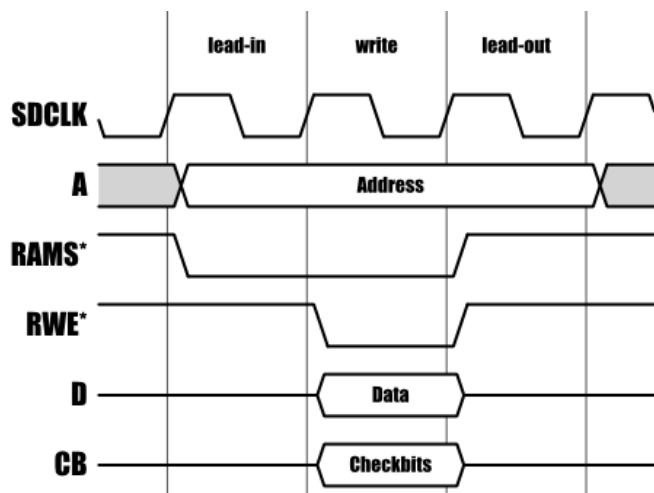

Figure 3-10. SRAM Read Access (no wait-states)

### 3.4.1.3 Write Access

An SRAM write access consists in an address lead-in cycle, a data write cycle and an address lead-out cycle. Each byte lane has an individual write strobe (RWE\*[]) to allow efficient byte and half-word writes.

Figure 3-11. SRAM Write Access (no wait-states)

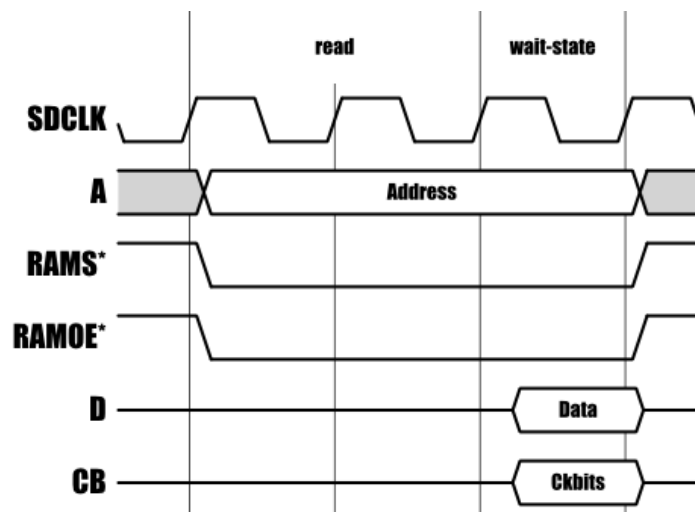

**Caution:** If EDAC protection is activated on the RAM area or a common write strobe is used for the full 32-bit data, read-modify-write shall be activated (MCFG2.rammw) so the EDAC checkbits integrity is preserved on sub-word writes.

### 3.4.1.4 Wait-States

For application accessing slow SRAM memories, the memory controller allows to insert wait-states during an SRAM read access (MCFG2.ramrws) and write access (MCFG2.ramwws). Up to 3 wait-states can be inserted.

Figure 3-12. SRAM Read Access with 1 Wait-State (MCFG2.ramrws = 1)

SRAM read/write access to bank 4 (RAMS\* [4]) can further be stretched when even more delay is needed (see "BRDY\* -Controlled Access" later in this chapter").

### 3.4.1.5 Data Bus Width

When configured for 32-bit SRAM (MCFG2.ramwdh = 00), D[31:0] shall be connected to the memory device(s). CB[7:0] shall be connected as well if EDAC protection is activated (MCFG3.pe = 1).

To support applications with limited memory and/or limited performance requirements, the SRAM area can be configured for 8-bit operations.

When configured for 8-bit SRAM (MCFG2.ramwdh = 00), D[31:24] shall be connected to the memory device(s).

Figure 3-13. 8-bit SRAM Interface

On an 8-bit memory, 32-bit load/store instructions are always performed as a sequence of 4 consecutive memory accesses. If EDAC protection is activated, a 5th byte read access is performed as well to retrieve the checkbits (see "Error Management EDAC" section later in this chapter). During a store operation, only the necessary bytes are written if EDAC protection is not activated. When EDAC protection is activated, the processor will always perform a full-word read-modify-write transaction on any sub-word store operation.

## 3.4.2 SDRAM Interface

### 3.4.2.1 Overview

The SDRAM controller allows addressing of up to 1 GB of SDRAM in 2 banks. SDRAM memory access control is performed using dedicated chip selects (SDCS\* [1:0]), data masks (SDDQM[3:0]), byte-write enables (SDWE\* [3:0]) and clock (SDCLK) signals.

SDRAM devices shall be 64 Mbit, 256 Mbit or 512 Mbit with 8 to 12 column-address bits, up to 13 row-address bits and exclusively 4 internal data banks. Only 32-bit data bus width is supported.

The SDRAMs address bus shall be connected to A[14:2] and the bank address to A[16:15]. Devices with less than 13 address pins should only use the less significant bits of A[14:2].

SDRAM banks map as follows:

- SDCS\* [0] and SDCS\* [1] decode 2 contiguous banks with a common programmable size (4 MB to 512 MB)
- SDCS\* [1:0] decode the upper half of the RAM area (0x60000000 0x7FFFFFFF) when the SRAM interface is enabled
- SDCS\* [1:0] decode the lower half of the RAM area (0x40000000 0x5FFFFFFF) when the SRAM interface is disabled

The SDRAM interface is controlled in the memory configuration registers (MCFG2 and MCFG3):

- interface can be enabled/disabled (MCFG2.se)
- bank size can be set from 4 MB to 512 MB (MCFG2.sdrbs)
- column size can be set from 256 to 4096 (MCFG2.sdrcls)
- commands can be sent to the devices (MCFG2.sdrcmd)
- timings parameters can be set (MCFG2.sdrcas, MCFG2.trp and MCFG2.trfc)
- auto-refresh can be enabled/disabled (MCFG2.sdrref) and programmed (MCFG3.scrv)
- EDAC protection<sup>1 2</sup> can be enabled/disabled (MCFG3.re)

Note: 1. EDAC protection activation common to SRAM and SDRAM interfaces.

Note: 2. Read-modify-write on sub-word operations simultaneously activated with EDAC.

### 3.4.2.2 Initialization

After reset, the SDRAM controller automatically performs an SDRAM initialization sequence. It consists in a PRECHARGE cycle, two AUTO-REFRESH cycles and a LOAD-MODE-REG cycle on both SDRAM banks simultaneously.

The controller programs the SDRAM to use page burst on read and single location access on write.

### 3.4.2.3 Timing Parameters

The SDRAM interface parameters can be programmed so read/write access to SDRAM devices is optimized:

**Table 3-2. SDRAM Programmable Timing Parameters**

Function	Parameter	Range	Unit	Control
CAS latency, RAS/CAS delay	tCAS, tRCD	2 3	clocks	MCFG2.sdrcas
Precharge to activate	tRP	2 3	clocks	MCFG2.trp
Auto-refresh command period	tRFC	3 11	clocks	MCFG2.trfc
Auto-refresh interval		10 32768	clocks	MCFG3.scrv

### 3.4.2.4 Refresh

The SDRAM controller embeds a refresh module. When enabled (MCFG2.sdrref = 1), it periodically issues an AUTO-REFRESH command to both SDRAM banks with a programmable period (MCFG3.scrv).

Depending on the SDRAM device used, the refresh period is typically 7.8 μs or 15.6 μs. The refresh period is calculated as

$$\text{Refresh period} = \frac{\text{Reload value} + 1}{\text{sdclk}_{\text{freq}}}$$

### 3.4.2.5 Commands

The SDRAM controller can issue three SDRAM commands (MCFG2.sdrcmd): PRE-CHARGE, AUTO-REFRESH and LOAD-MODE-REG. The command field is cleared after a command has been executed.

If the LOAD-MODE-REG command is issued, the programmed CAS delay is used (MCFG2.sdrcas) while remaining fields are fixed (page read burst, single location write and sequential burst).

A LOAD-MODE-REG command shall be issued whenever the programmed CAS delay is updated.

### 3.4.2.6 Read Access

A read access consists in several phases:

- an ACTIVATE command to the desired bank and row
- a READ command after the programmed CAS delay
- data read(s) (single or burst with no idle cycles if requested on the internal bus)
- a PRE-CHARGE command to terminate the access (no bank left open)

### 3.4.2.7 Write Access

A write access consists in several phases:

- an ACTIVATE command to the desired bank and row
- a WRITE command after the programmed CAS delay
- data read(s) (single or burst with no idle cycles if requested on the internal bus)
- a PRE-CHARGE command to terminate the access (no bank left open)

## 3.5 Write Protection

Two write protection schemes are provided to protect the RAM area against accidental over-writing: the “Start/End Address Scheme” and the “Tag/Mask Address Scheme”.

### 3.5.1 Start/End Address Scheme

Start/End Address scheme protection is implemented as 2 write protection units capable of each controlling supervisor and/or user write access inside/outside of a memory segment of any arbitrary size.

- each unit *n* is configured by two write protection registers (WPSTAn and WPSTOn):
- the unit can be enabled/disabled<sup>1</sup> in supervisor mode<sup>2</sup> (WPSTOn.su) and in user mode<sup>3</sup> (WPSTOn.us)
- the segment is defined by a START address<sup>4</sup> (WPSTAn.start) and an END address<sup>4</sup> (WPSTOn.end)
- protection can be performed inside/outside the segment (WPSTAn.bp)

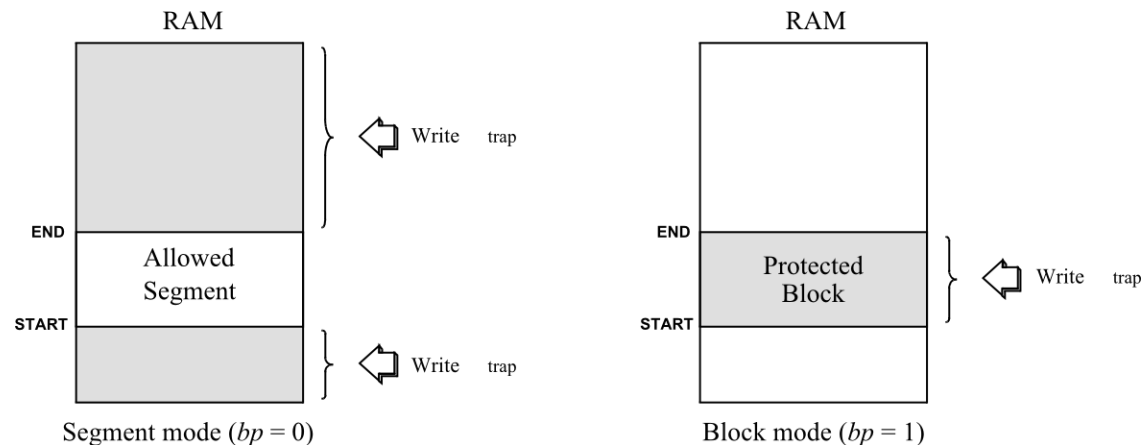

Note: 1. The unit is enabled as soon as one of the two modes is enabled

Note: 2. The DSU communication interface has supervisor status when accessing the RAM area

Note: 3. The PCI interface (DMA and Target) has user status when accessing the RAM area

Note: 4. Address is a 32-bit word-aligned offset from the start of the RAM area (0x40000000)

**Figure 3-14. Start/End Address Scheme Protection Overview**

The protection is based on a segment of any arbitrary size in the RAM address space (4 bytes to 1 GB):

**Table 3-3. Write Address Comparison**

bit num	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
field	01															Most significant write address bits											word					

The most significant bits of the write address are simply compared against the START and the END address of the segment (both boundaries included) to determine if the write address is inside the defined segment or in the block (outside of this segment).

If the write protection unit is enabled for the current IU mode (user or supervisor) and a block or segment protection error is detected, the write access is cancelled and a write\_error trap (0x2B) is generated.

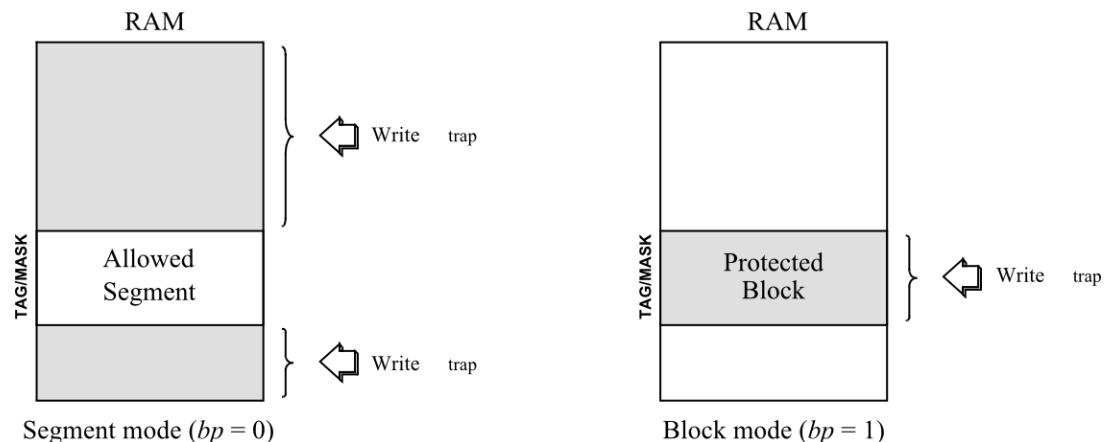

### 3.5.2 Tag/Mask Address Scheme

Tag/Mask address scheme protection is implemented as two write protection units capable of each controlling write access inside/outside of a binary aligned memory segment in the range of 32 KB - 1 GB.

Each unit *n* is configured by a write protection register (WPR<sub>*n*</sub>):

- the unit can be enabled/disabled (WPR<sub>*n*</sub>.en)
- a TAG specifies the 15 most significant bits of the segment address (WPR<sub>*n*</sub>.tag)
- a MASK specifies which bits within the TAG are relevant (WPR<sub>*n*</sub>.mask)
- protection can be performed inside/outside the segment (WPR<sub>*n*</sub>.bp)

Figure 3-15. Tag/Mask Address Scheme Protection Overview

The protection is based on a segmentation of the RAM address space to define a segment in the range of 32 KB up to 1 GB:

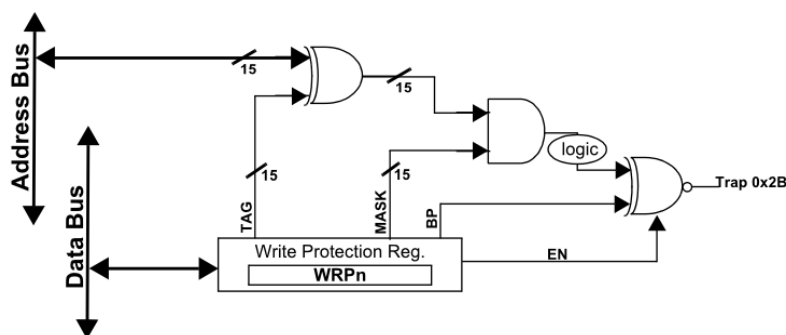

Table 3-4. Write Address Segmentation

bit num	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
field	01		Most significant write address bits														32 KB minimum area															

The most significant bits of the write address are XORed with the TAG, and the result is then ANDed with the MASK. If the final result is zero, the write address is in the defined segment, otherwise the write address is in the block (outside of this segment).

If the write protection unit is enabled and a block or segment protection error is detected, the write access is cancelled and a write\_error trap (0x2B) is generated.

Figure 3-16. Segment/Block Protection Unit

### 3.5.3 Mixed Protection Schemes

It is possible to simultaneously use the Start/End Address and the Address/Mask write protection schemes. In that case (at least one unit is enabled in each scheme), the following rules applies:

- when all enabled units are configured in block mode, a write\_error trap (0x2B) is generated if at least one unit signals a protection error.
- when at least one enabled unit operates in segment mode, a write\_error trap (0x2B) is generated only if all units configured in segment mode signal a protection error.

### 3.6 BRDY\* -Controlled Access

The BRDY\* signal can be used to further stretch a read or write access and is enabled separately for the PROM area (MCFG1.pbrdy), the SRAM area decoded by RAMS\* [4] (MCFG2.rambrdy) and the I/O area (MCFG1.iobrdy).

An access is always performed with at least the pre-programmed number of wait-states specified in the appropriate memory configuration register (MCFG1 & MCFG2), but is further stretched until BRDY\* is asserted.

Termination of a BRDY\* -controlled access can be performed in two different modes:

- synchronous mode (MCFG1.abrdy = 0): BRDY\* is sampled on the rising edge of the clock and shall meet the setup (t19) and hold (t20) timing constraints (see "AC Characteristics").
- asynchronous mode (MCFG1.abrdy = 1): BRDY\* shall be kept asserted for 1.5 clock cycle so it is guaranteed to meet at least one rising edge of the clock (setup/hold timing constraints do not apply anymore). Data in a read access shall be kept stable until de-assertion of the device select (ROMS\* [0]/ ROMS\*[1] or RAMS\* [4] or IOS\* , as appropriate) and output-enable (OE\* or RAMOE\* [4], as appropriate) signals.

The access is terminated on the rising edge of the clock that immediately follows the detection of the asserted BRDY\*.

### 3.7 Memory Mapped Reconfigurable Unit

The embedded memory controller shares its interface with the reconfigurable unit so that it is possible to map the reconfigurable unit on the standard address map of the processor unit. All the signals from the PROM, IO and SRAM interface are shared between the two units making possible the use of the reconfigurable unit in any of the memory area supported by the processor.

The SDRAM control signals are not made available for the reconfigurable unit.

The complete address, data and checkbit buses are shared between the two units with respect to the following assignment:

**Table 3-5. IO connexions with the memory interface**

**Caution:** Warning: These shared IO have to be correctly configured to avoid signal reflexions and damages on the IO of the ATF697FF component. In particular, severals outputs on the same IO should not be configured in output at the same time.

## 4. EDAC management

### 4.1 Overview

The ATF697FF processor implements on-chip error detection and correction (EDAC). It can correct any single-bit error and detect double-bit errors in a 32-bit word.

### 4.2 EDAC Capability Mapping

EDAC is available on PROM, SRAM and SDRAM memory areas.

Table 4-1. External Memory EDAC Capability

Address Range	Area		EDAC Protected
0x00000000 0x1FFFFFFF	PROM	8 bits	yes
		32 bits	yes
0x20000000 0x3FFFFFFF	I/O	All	no
0x40000000 0x7FFFFFFF	SRAM	8 bits	yes
		32 bits	yes
	SDRAM	32 bits	yes

#### 4.2.1 PROM Protection

When EDAC is activated on the PROM area<sup>1</sup> (MCFG3.pe = 1), error detection and correction is performed on every instruction fetch and data load in that area.

Note: 1. Upon reset, EDAC on the PROM area is automatically configured from the value read on the GPIO[2] pin. By driving GPIO[2] high during reset, it is possible to enable EDAC on PROM on boot.

#### 4.2.2 RAM Protection

When EDAC is activated on the RAM area<sup>1 2</sup> (MCFG3.re = 1), error detection and correction is performed on every instruction fetch and data load in that area.

Note: 1. When EDAC is enabled on the RAM area, read-modify-write on the SRAM (MCFG2.rammw) shall be enabled as well so the integrity of the EDAC checkbits is preserved on sub-word writes.

Note: 2. Activating EDAC on the RAM area automatically enables read-modify-write on sub-word writes to the SDRAM.

**Caution:** The RAM area shall always be initialized with 32-bit word writes prior to EDAC activation so further sub-word writes (performed as 32-bit read-modify-write atomic operations) always successfully pass the initial read & check step (see "Read Access").

### 4.3 Operation

When enabled, the EDAC operates on every access to the external memory.

### 4.3.1 Hamming Code

For each word, a 7-bit checksum is generated according to the following equations:

$$CB0 = D0 \wedge D4 \wedge D6 \wedge D7 \wedge D8 \wedge D9 \wedge D11 \wedge D14 \wedge D17 \wedge D18 \wedge D19 \wedge D21 \wedge D26 \wedge D28 \wedge D29 \wedge D31$$

$$CB1 = D0 \wedge D1 \wedge D2 \wedge D4 \wedge D6 \wedge D8 \wedge D10 \wedge D12 \wedge D16 \wedge D17 \wedge D18 \wedge D20 \wedge D22 \wedge D24 \wedge D26 \wedge D28$$

$$CB2 = \overline{D0 \wedge D3 \wedge D4 \wedge D7 \wedge D9 \wedge D10 \wedge D13 \wedge D15 \wedge D16 \wedge D19 \wedge D20 \wedge D23 \wedge D25 \wedge D26 \wedge D29 \wedge D31}$$

$$CB3 = \overline{D0 \wedge D1 \wedge D5 \wedge D6 \wedge D7 \wedge D11 \wedge D12 \wedge D13 \wedge D16 \wedge D17 \wedge D21 \wedge D22 \wedge D23 \wedge D27 \wedge D28 \wedge D29}$$

$$CB4 = D2 \wedge D3 \wedge D4 \wedge D5 \wedge D6 \wedge D7 \wedge D14 \wedge D15 \wedge D18 \wedge D19 \wedge D20 \wedge D21 \wedge D22 \wedge D23 \wedge D30 \wedge D31$$

$$CB5 = D8 \wedge D9 \wedge D10 \wedge D11 \wedge D12 \wedge D13 \wedge D14 \wedge D15 \wedge D24 \wedge D25 \wedge D26 \wedge D27 \wedge D28 \wedge D29 \wedge D30 \wedge D31$$

$$CB6 = D0 \wedge D1 \wedge D2 \wedge D3 \wedge D4 \wedge D5 \wedge D6 \wedge D7 \wedge D24 \wedge D25 \wedge D26 \wedge D27 \wedge D28 \wedge D29 \wedge D30 \wedge D31$$

### 4.3.2 Write Access

When the processor performs a write access to an EDAC protected memory, it also outputs the 7-bit EDAC checkbits on the CB[6:0] pins (CB[7] always driven low unless EDAC testing is enabled).

### 4.3.3 Read Access

When the processor performs a read access to an EDAC protected memory, the checkbits read together with the data are compared against checkbits generated by the EDAC from the same read data. Any discrepancy yields an error and a syndrome is computed to further qualify the error as correctable (single-bit error) or uncorrectable (double-bit error).

### 4.3.4 Correctable Error

A single-bit error qualifies as a correctable error. The correction is performed on-the-fly inside the processor during the current access and no timing penalty is incurred.

The correctable error event is reported in the fail address register (FAILAR) and in the fail status register (FAILSR). If unmasked, interrupt 1 (trap 0x11) is generated.

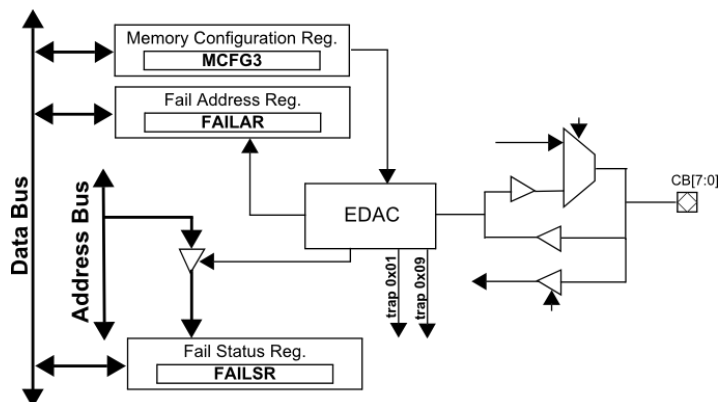

The single-bit error remains in memory until a software-initiated rewrite is performed at the faulty memory location.

### 4.3.5 Uncorrectable Error

A double-bit error qualifies as an uncorrectable error:

- an `instruction_access_exception` trap (0x01) is generated if an instruction fetch is in progress
- a `data_access_exception` trap (0x09) is generated if a data load is in progress

Figure 4-1. EDAC overview

#### 4.4 EDAC on 8-bit Memories

EDAC protection on 8-bit memories can be performed as well. CB[7:0] is not used and the EDAC checkbits are stored in the upper part of the 8-bit memory bank where the protected data reside.

When EDAC is enabled:

- an instruction fetch or a data load is performed as a burst of 4 read access to retrieve the 4 bytes and a 5th read access to retrieve the checkbits
- any word and sub-word store can be performed in RAM
- only byte store shall be performed in PROM

The protected memory bank is partitioned as follows:

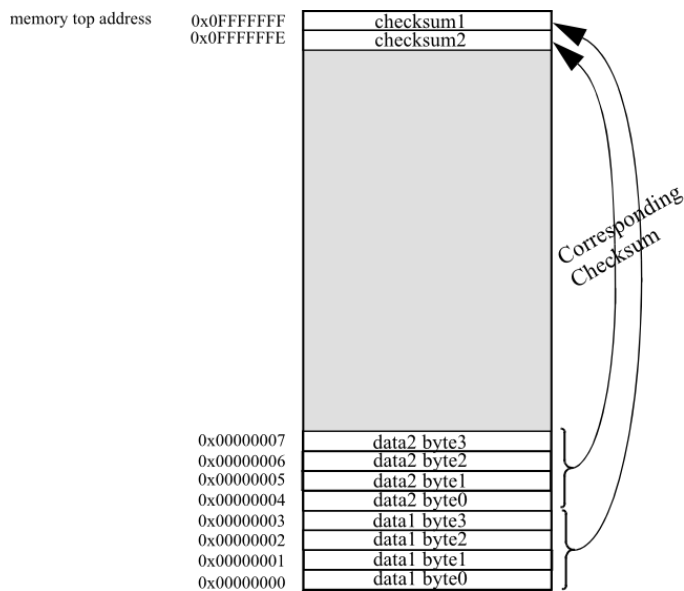

- lower 80% of the memory bank available as program or data memory
- upper 20% of the memory bank allocated to the EDAC checkbits (a maximum of 4 unusable bytes before the checkbit area)

Accessing the EDAC checkbits is performed as follows:

- start address from the topmost byte in the same memory bank (no bank size information needed)
- $\text{addrcheckbits} = \text{addrbank-top} ((\text{addrdata} \text{addrbank-start}) / 4)$

checkbits bytes allocated downwards (address bits inversion technique used)

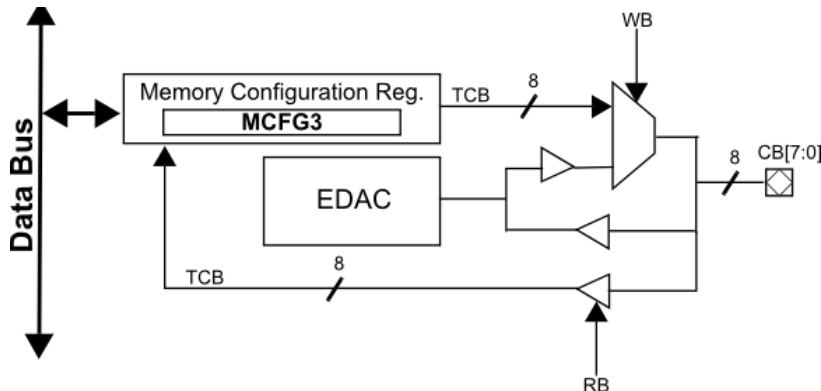

Figure 4-2. 8-bit EDAC-Protected Memory Organization

## 4.5 EDAC Testing

Operation of the EDAC can be bypassed for testing purpose and is controlled in a memory configuration register (MCFG3).

### 4.5.1 EDAC testing overview

### 4.5.2 Write Test

When EDAC write bypass is enabled (MCFG3.wb = 1), the test checkbits (MCFG3.tcb) replace the EDAC generated checkbits during a data store.

### 4.5.3 Read Test

When EDAC read diagnostic is enabled (MCFG3.rb = 1), the test checkbits (MCFG3.tcb) are updated<sup>1</sup> with the read checkbits during a data load or an instruction fetch.

Note: 1. The EDAC test routine shall be executed entirely from the instruction cache (when activated) or from an area without EDAC activated and different from the one being accessed. Otherwise the checkbits read during instruction fetch will overwrite those from the area to be tested.

## 5. Bus exception

A PROM, SRAM or I/O read/write access error can be signalled to the processor by asserting the BEXC\* signal which is sampled together with the read/written data, if enabled in the memory controller (MCFG1.bexc = 1):

- an instruction\_access\_exception trap (0x01) is generated if an instruction fetch is in progress
- a data\_access\_exception trap (0x09) is generated if a data load is in progress
- a write\_error trap (0x2B) is generated if a data store is in progress

## 6. CACHES

### 6.1 Overview

The ATF697FF processor implements a Harvard architecture with separate instruction and data bus, each connected to an independent cache controller. In order to improve the speed performance of the processor, multi-way caches are used to provide a faster access to instructions and data.

The PROM and RAM areas, which represent most of the external memory areas, can be cached.

**Table 6-1. Caching Capability**

Address Range	Area	Cacheability
0x00000000 0x1FFFFFFF	PROM	Cacheable
0x20000000 0x3FFFFFFF	I/O	Non-cacheable
0x40000000 0x7FFFFFFF	RAM	Cacheable
0x80000000 0x8FFFFFFF	Registers	Non-cacheable
0x90000000 0x9FFFFFFF	DSU	Non-cacheable
0xA0000000 0xFFFFFFFF	PCI	Non-cacheable

### 6.2 Operation

An associative cache is organized in sets, each set being divided into cache lines. Each line has a cache tag associated with it consisting of a tag field and a valid field with one valid bit for each 4-byte cache data sub-block.

The cache replacement policy used for both instruction and data caches is based on the LRU algorithm: new entries are allocated in a cache until the cache is full, then least recently used entries are replaced with new entries not already present in the cache.

A cache always operates in one of the three modes: disabled, enabled or frozen.

#### 6.2.1 Disabled Mode

No cache operation is performed and fetch/load requests are passed directly to the memory controller.

#### 6.2.2 Enabled Mode

On a cache miss to a cacheable location, the fetch/load request is passed to the memory controller and the corresponding tag and data line are updated with the retrieved instruction/data. Otherwise, the instruction/data is directly retrieved from the cache and forwarded to the IU/FPU.

#### 6.2.3 Frozen Mode

The cache is accessed as if it was enabled, but no new line is allocated on a cache miss.

If the freeze-on-interrupt feature is activated, the corresponding cache is automatically frozen when an asynchronous interrupt is taken. This can be beneficial in real-time system to allow a more accurate calculation of worst-case execution time for an interrupt service routine (ISR). Execution of the interrupt handler will not evict any cache line so when control is returned to the interrupted task, the cache state is identical to what it was before the interrupt.

If a cache was frozen by an interrupt, it can only be enabled again in software. This is typically done at the end of the interrupt service routine before control is returned to the interrupted task.

## 6.2.4 Parity Protection

Cache tag/data error protection is implemented using two parity bits per tag and per 4-byte data sub-block. The tag parity is generated from the tag value, the valid bits and the tag address. By including the tag address, it is also possible to detect errors in the cache ram address decoding logic. Similarly, the data subblock parity is derived from the sub-block address and the sub-block data. The parity bits are written simultaneously with the associated tag or sub-block and checked on each access. The two parity bits correspond to the parity of odd and even tag/data bits.

If a tag parity error is detected during a cache access, a cache miss is generated and the tag/data is automatically updated. All valid bits except the one corresponding to the newly loaded data are cleared. Each tag error is reported in the cache tag error counter, which is incremented until the maximum count is reached.

If a data sub-block parity error occurs, a miss is also generated but only the failed sub-block is updated with fetched/loaded data. Each error is reported in the cache data error counter, which is incremented until the maximum count is reached.

## 6.3 Instruction Cache

### 6.3.1 Overview

The ATF697FF processor instruction cache is implemented as a 4-way associative cache of 32 KB, organized in 4 sets of 8 KB. Each instruction cache set is divided into cache lines of 32 bytes (8 instructions). Each line has a cache tag associated with it consisting of a tag field and a valid bit field per instruction.

### 6.3.2 Cache Control

The instruction cache operation is controlled in the cache control register (CCR):

- operating mode is reported and can be changed (CCR.ics)
- cache can be frozen on interrupts (CCR.if)
- cache flush can be initiated (CCR.fi)
- pending cache flush is reported (CCR.ip)
- burst fetch is reported and can be activated (CCR.ib)
- up to 3 cache tag/data errors are reported in counters (CCR.ite and CCR.ide), which shall be cleared to register new events

### 6.3.3 Operation

#### 6.3.3.1 Instruction Fetch

On an instruction cache fetch-miss to a cacheable location, an instruction (4 bytes) is loaded into the cache from external memory.

#### 6.3.3.2 Burst Fetch

If instruction burst fetch is enabled in the cache control register (CCR.ib = 1), the cache line is filled from main memory starting at the missed address and until the end of the line.

At the same time, the instructions are forwarded to the IU (streaming). If the IU cannot accept the streamed instructions due to internal dependencies or a multi-cycle instruction, the IU is halted until the line fill is completed. If the IU executes a control transfer instruction during the cache line fill (Bicc/CALL/ JMWPL/RETT/Ticc), the cache line fill is terminated on the next fetch.

If instruction burst fetch is enabled, instruction streaming is enabled even when the cache is disabled. In this case, the fetched instructions are only forwarded to the IU and the cache is not updated.

### 6.3.3.3 Cache Flush

The instruction cache is flushed by executing the FLUSH instruction, or by activating the instruction cache flush in the cache control register (CCR.fi = 1).

The flush operation takes one clock cycle per cache line and set. The IU is not halted during the cache flush but the cache behaves as if it was disabled. When the flush operation is completed, the cache resumes the state (disabled, enabled or frozen) indicated in the cache control register (CCR.ics).

### 6.3.3.4 Error reporting

If a memory access error occurs during a line fill with the IU halted, the corresponding valid bit in the cache tag is not set. If the IU later fetches an instruction from the failed address, a cache miss will occur, triggering a new access to the failed address.

If the error remains, an instruction\_access\_error trap (0x01) is generated.

## 6.4 Data Cache

### 6.4.1 Overview

The ATF697FF processor data cache is implemented as a 2-way associative cache of 16 KB, organized in 2 sets of 8 KB. Each data cache set is divided into cache lines of 16 bytes (4 words). Each line has a cache tag associated with it consisting of a tag field and a valid bit field per word.

### 6.4.2 Cache Control

The data cache operation is controlled in the cache control register (CCR):

- operating mode is reported and can be changed (CCR.dcs)
- cache can be frozen on interrupts (CCR.df)
- cache flush can be initiated (CCR.fd)
- pending cache flush is reported (CCR.dp)
- cache snooping can be activated (CCR.ds)
- up to 3 cache tag/data errors are reported in counters (CCR.dte and CCR.dde), which shall be cleared to register new events

### 6.4.3 Operation

#### 6.4.3.1 Data Load

On a data cache read-miss to a cacheable location, 1 word of data (4 bytes) is loaded into the cache from external memory.

#### 6.4.3.2 Data Store

The write policy for stores is write-through with update on write-hit and no-allocate on write-miss. An internal write buffer of three 32-bit words is used to temporarily hold store data until it is effectively written into the external device. For half-word and byte stores, the stored data is replicated into proper byte alignment for writing to a word-addressed device before being loaded into the write buffer.

The write buffer is emptied prior to a load-miss/cache-fill sequence to avoid any stale data from being read into the data cache.

#### 6.4.3.3 Cache Flush

The data cache is flushed by executing the FLUSH instruction, or by activating the data cache flush in the cache control register (CCR.fd = 1).

The flush operation takes one clock cycle per cache line and set. The IU is not halted during the cache flush but the cache behaves as if it was disabled. When the flush operation is completed, the cache resumes the state (disabled, enabled or frozen) indicated in the cache control register (CCR.dcs).

#### 6.4.3.4 Cache Snooping

The data cache can perform snooping on the internal bus. When snooping is enabled (CCR.ds = 1), the data cache controller monitors write accesses performed either by the PCI DMA controller, or by the PCI target controller or by the DSU communication module. When a write access is performed to a cacheable memory location, the corresponding cache line is invalidated in the data cache if present. Cache snooping has no overhead and does not affect performance.

#### 6.4.4 Error Reporting

If a memory access error occurs during a data load, the corresponding valid bit in the cache tag is set and a `data_access_error` trap (0x09) is generated.

Since the processor executes in parallel with the write buffer, a write error may not cause an exception to the store instruction. Depending on memory and cache activity, the external memory write access may not occur until several clock cycles after the store instructions has completed. If a write error occurs, the currently executing instruction will take a `write_error` trap (0x2B).

**Caution:** The `write_error` trap handler shall flush the data cache since a write hit would update the cache while the memory would keep the old value due the write error.

### 6.5 Diagnostic Cache Access

Tags and data in the instruction and data cache can be accessed through ASI address space by executing LDA and STA instructions (only the least-significant nibble of the ASI field -ASI[3:0]-is used for mapping to the alternate address space). Address bits making up the cache offset are used to index the tag to be accessed while the least significant bits of the bits making up the address tag are used to index the cache set.

The following table summarizes the ASI allocation on the ATF697FF processor.

**Table 6-2. ASI Usage**

ASI	Usage
0x0, 0x1, 0x2, 0x3	Force cache miss (replace if cacheable)
0x4, 0x7	Force cache miss (update on hit)
0x5	Flush instruction cache
0x6	Flush data cache
0x8	User instruction (replace if cacheable)
0x9	Supervisor instruction (replace if cacheable)
0xA	User data (replace if cacheable)
0xB	Supervisor data (replace if cacheable)
0xC	Instruction cache tags
0xD	Instruction cache data
0xE	Data cache tags

ASI	Usage
0xF	Data cache data

Note: Please refer to "The SPARC Architecture Manual Version 8" document for detailed information on ASI usage. The tags can be directly read/written by executing an LDA/STA instruction with ASI=0xC for instruction cache tags and ASI=0xE for data cache tags. The cache line and the cache set are indexed by the address bits making up the cache offset and the least significant bits of the address bits making up the address tag.

Similarly, the data sub-blocks are read/written by executing an LDA/STA instruction with ASI=0xD for instruction cache data and ASI=0xF for data cache data..

Note: Diagnostic cache access is not possible during a cache flush operation and will cause a data\_exception trap (0x09) if attempted.

## 7. Traps and Interrupts

### 7.1 Overview

The ATF697FF processor supports two types of traps:

- synchronous traps
- asynchronous traps also called interrupts.

Synchronous traps are caused by the hardware responding to a particular instruction. They occur during the instruction that caused them. Asynchronous traps occur when an external event interrupts the processor. They are not related to any particular instruction and occur between the execution of instructions.

A trap is a vectored transfer of control to the supervisor through a special trap table that contains the first four instructions of each trap handler. The trap base address (TBR) of the table is established by the supervisor and the displacement, within the table, is determined by the trap type.

A trap causes the current window pointer to advance to the next register window and the hardware to write the program counters (PC & NPC) into two registers of the new window.

### 7.2 Synchronous Traps

The ATF697FF processor follows the general SPARC trap model. The table below shows the implemented traps and their individual priority.

**Table 7-1. Trap Overview**

Trap	Trap Type	Priority	Description
reset	n/a <sup>1</sup>	1	Power-on reset
write_error	0x2B	2	Write buffer error
instruction_access_exception	0x01	3	Error during instruction fetch Edac uncorrectable error during instruction fetch
illegal_instruction	0x02	5	UNIMP or other un-implemented instruction
privileged_instruction	0x03	4	Execution of privileged instruction in user mode
fp_disabled	0x04	6	FP instruction while FPU disabled
cp_disabled	0x24		Co-processor instruction while co-processor disabled
watchpoint_detected	0x0B	7	Instruction or data watchpoint match
window_overflow	0x05	8	SAVE into invalid window
window_underflow	0x06		RESTORE into invalid window
register_hardware_error	0x20	9	Register file uncorrectable EDAC error
mem_address_not_aligned	0x07	10	Memory access to un-aligned address
fp_exception	0x08	11	FPU exception

Trap	Trap Type	Priority	Description
data_access_exception	0x09	13	Access error during load or store instruction
tag overflow	0x0A	14	Tagged arithmetic overflow
divide_exception	0x2A	15	Divide by zero
trap_instruction	0x80 0xFF	16	Software trap instruction (Ticc)

Note: 1. The reset trap is a special case of the external asynchronous trap type: the trap type field of the trap base register (TBR.tt) is never modified so if the processor goes to error mode, a post-mortem can later be conducted on what caused the error, if any.

### 7.3 Traps Description

- reset A reset trap occurs immediately after the PROC\_RESET\* signal is deasserted.
- write\_error An error exception occurred on a data store to memory.
- instruction\_access\_exception A blocking error exception occurred on an instruction access.
- illegal\_instruction An attempt was made to execute an instruction with an unimplemented opcode, or an UNIMP instruction, or an instruction that would result in illegal processor state.
- privileged\_instruction An attempt was made to execute a privileged instruction while not in supervisor mode (PSR.s = 0).
- fp\_disabled An attempt was made to execute an FPU instruction while the FPU is not enabled.
- cp\_disabled An attempt was made to execute a co-processor instruction (there is no co-processor).
- watchpoint\_detected An instruction fetch memory address or load/store data memory address matched the contents of an active watchpoint register.
- window\_overflow A SAVE instruction attempted to cause the current window pointer (CWP) to point to an invalid window in the window invalid mask register (WIM).
- window\_underflow A RESTORE or RETT instruction attempted to cause the current window pointer (CWP) to point to an invalid window in the window invalid mask register (WIM).
- register\_hardware\_error An error exception occurred on a read only register access. A register file uncorrectable error was detected.
- mem\_address\_not\_aligned A load/store instruction would have generated a memory address that was not properly aligned according to the instruction, or a JMPL or RETT instruction would have generated a non-word-aligned address.
- fp\_exception An FPU instruction generated an IEEE-754\_exception and its corresponding trap enable mask bit (FSR.tem) was set, or the FPU instruction was unimplemented, or the FPU instruction did not complete, or there was a sequence or hardware error in the FPU. The type of floating-point exception is encoded in the FPU state register (FSR.ftt).
- data\_access\_exception A blocking error exception occurred on a load/store data access. EDAC uncorrectable error.
- tag\_overflow A tagged arithmetic instruction was executed, and either arithmetic overflow occurred or at least one of the tag bits of the operands was non zero.
- trap\_division\_by\_zero An integer divide instruction attempted to divide by zero.
- trap\_instruction A software instruction (Ticc) was executed and the trap condition evaluated to true.

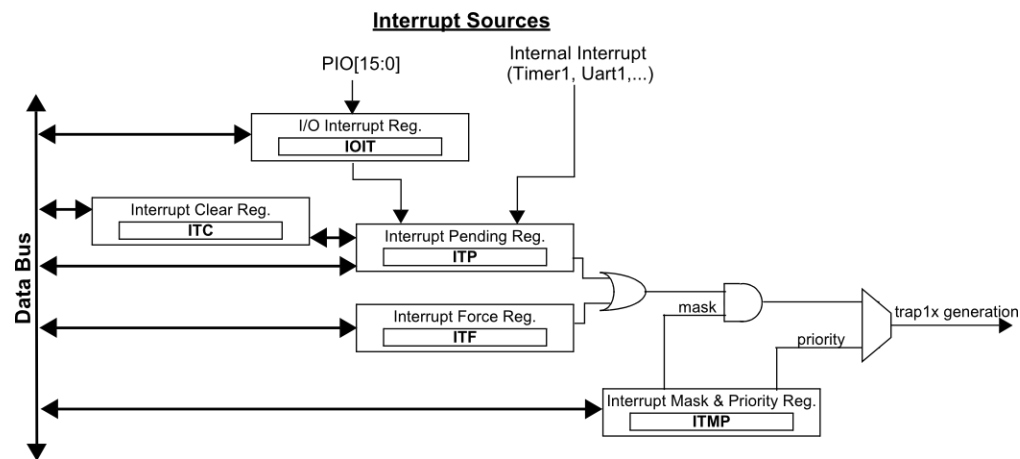

When multiple synchronous traps occur at the same cycle (i.e hardware errors), the highest priority trap is taken and lower priority traps are ignored.

## 7.4 Asynchronous Traps / Interrupts

The ATF697FF processor handles up to 15 interrupts. The interrupt controller is used to prioritize and propagate interrupts requests from internal peripherals and external devices to the IU.

Figure 7-1. Interrupt Controller Block Diagram

### 7.4.1 Operation

Interrupts are controlled in the interrupt mask and priority register (ITMP):

- interrupts requests can be masked (ITMP.imask) so they will not trigger an interrupt
- interrupt requests can have a low/high priority level (ITMP.ilevel)

When an interrupt request is generated, the corresponding bit is set in the interrupt pending register (ITP.ipend[]) only if the interrupt is not masked (ITMP.imask[] = 0).

Then all pending interrupts are forwarded to the priority selector. The pending interrupt (ITP.ipend[]) with the highest number on the high priority level (ITMP.ilevel[] = 1) is selected and forwarded to the IU. If no pending interrupt exists with a high priority level, the pending interrupt with the highest number on the low priority level (ITMP.ilevel[] = 0) is selected and forwarded to the IU.

Interrupts can also be forced by setting the corresponding bit in the interrupt force register (ITF.iforce[] = 1). Forcing is effective only if the corresponding interrupt is not masked (ITMP.imask[] = 0). A forced interrupt never shows up as pending.

Pending interrupts can be cleared by setting the appropriate bit in the interrupt clear register (ITC.iclear[] = 1).

When the IU acknowledges an interrupt, the corresponding pending bit is automatically cleared (ITP.ipend[] = 0) unless it was forced in the interrupt force register (ITF.iforce[] = 1). If the interrupt was forced, the IU acknowledgement rather clears the force bit (ITF.iforce[] = 0).

### 7.4.2 Interrupts List

The following table presents the interrupts assignment:

**Table 7-2. Interrupt Overview**

Interrupt	Trap Type	Source
15	0x1F	I/O interrupt 7 <sup>1</sup>
14	0x1E	PCI
13	0x1D	I/O interrupt 6
12	0x1C	I/O interrupt 5
11	0x1B	DSU trace buffer
10	0x1A	I/O interrupt 4
9	0x19	Timer 2
8	0x18	Timer 1
7	0x17	I/O interrupt 3
6	0x16	I/O interrupt 3
5	0x15	I/O interrupt 1
4	0x14	I/O interrupt 0
3	0x13	UART 1
2	0x12	UART 2
1	0x11	Hardware error <sup>2</sup>

Note: 1. Interrupt 15 cannot be filtered by the processor interrupt level in the IU (PSR.pil) and shall be used with care.

Note: 2. Interrupt 1 is triggered each time a new hardware error is reported (FAILAR.hed) so the application ultimately knows about any hardware error that was detected (bus exception, write protection error, EDAC correctable and uncorrectable external memory error, PCI initiator error or PCI target error).

### 7.4.3 I/O Interrupts

As an alternate function of the general purpose interface, the ATF697FF processor can handle interrupts from external devices. Up to 8 external interrupts can be programmed at the same time. The external interrupts are assigned to interrupt 4, 5, 6, 7, 10, 12, 13 and 15.

There are two registers for configuring I/O interrupts:

- IO interrupt 0, 1, 2 and 3 are controlled by IOIT1
- IO interrupt 4, 5, 6 and 7 are controlled by IOIT2

Each I/O interrupt is controlled through 4 parameters in the appropriate configuration register (n = 1 & x in [0:3] or n = 2 & x in [4:7]):

- the interrupt can be enabled or disabled (IOITn.enx)
- the interrupt source can be chosen among GPIO[15:0] and D[15:0]<sup>1</sup>(IOITn.iselx)
- the interrupt can be level-triggered<sup>2</sup> or edge-triggered<sup>2</sup> (IOITn.lex)
- the interrupt polarity can be high/low<sup>2</sup> when level-triggered or rising/falling<sup>2</sup> when edge-triggered (IOITn.plx)

Note: 1. D[15:0] can be used as part of the general-purpose I/O interface only when all the memory areas (ROM, SRAM & I/O) are 8-bit wide and the SDRAM interface is not enabled.

Note: 2. Whatever the chosen trigger mode, the I/O inputs are sampled on the rising edge of the system clock. If generated synchronously, the signal driving the I/O interrupt shall meet the required setup and hold constraints (see "Electrical Characteristics"). If generated asynchronously, the signal driving the I/O interrupt shall be maintained for a minimum of 1.5 clock cycles so at least 1 active sample can be made.

The following table summarizes the I/O interrupt trigger configurations.

**Table 7-3. I/O Interrupt Trigger Configuration**

IOITn.lex	IOITn.plx	Trigger
0	0	low level
0	1	high level
1	0	falling edge
1	1	rising edge

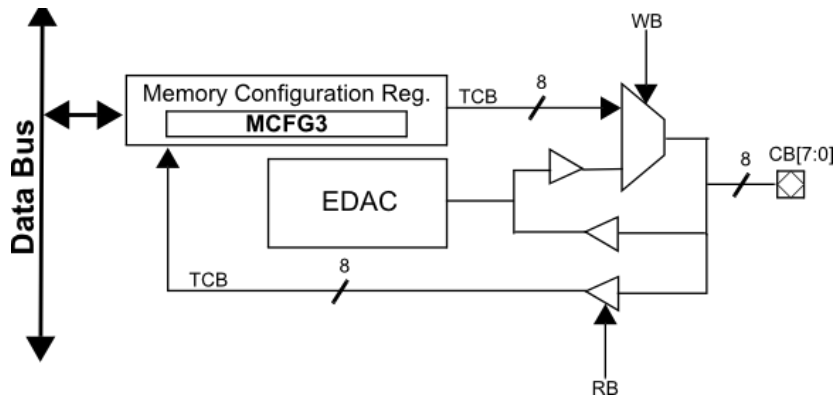

## 8. TIMER

The timer unit implements two 32-bit timers, one 32-bit watchdog and one 10-bit shared prescaler.

### 8.1 Prescaler

The prescaler is an internal device shared by the two timers and the watchdog.

Figure 8-1. Prescaler Block Diagram

The prescaler operation is controlled by two registers (SCAC and SCAR):

- the prescaler is always enabled
- the counter (SCAC.cnt) is clocked by the system clock and decremented on each clock cycle
- the counter is reloaded from the prescaler reload register (SCAR.rl) after it underflows and a tick pulse is generated for the two timers and the watchdog
- after reset, the prescaler counter & reload registers are initialized to the minimum division rate

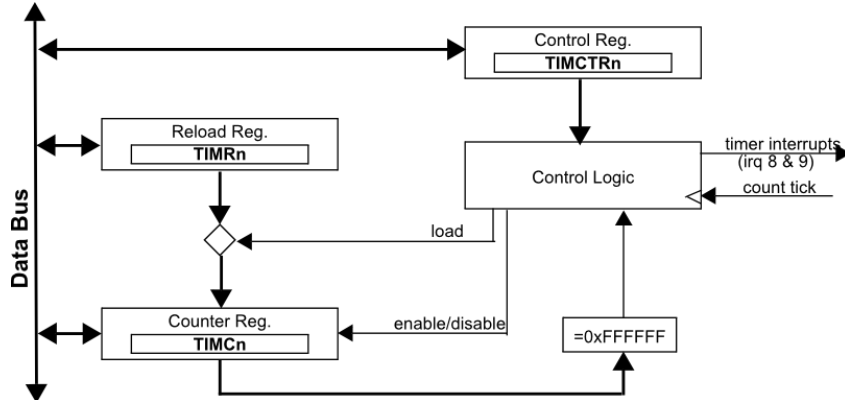

The effective division rate is therefore equal to the prescaler reload register value + 1.

The two timers and the watchdog share the same decremter, so the minimum possible prescaler division rate is 4 to allow processing of the two timers and the watchdog.

## 8.2 Timer 1 & Timer 2

Timer1 and Timer2 are two general purpose 32-bit timers. They share the same decremter with the watchdog.

Figure 8-2. Timer 1/2 Block Diagram

Each timer n operation is controlled by a dedicated set of timer control registers (TIMCTRn, TIMRn and TIMCn):

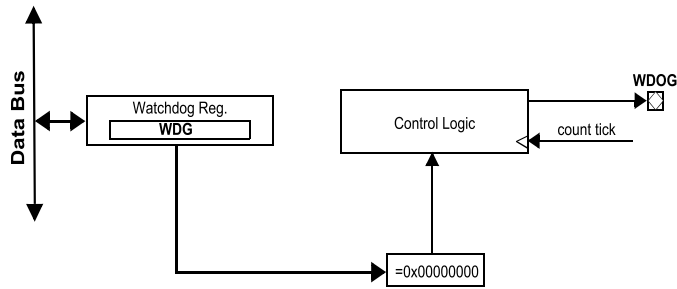

- a timer can be enabled/disabled (TIMCTRn.en)
- the counter (TIMCn.cnt) is decremented each time the prescaler generates a tick pulse
- the counter can be manually loaded (TIMCTRn.ld) from the reload register (TIMCTRn.rv)
- the counter can be configured to stop or to automatically reload (TIMRn.rl) after it underflows

Each time a timer underflows, a timer-dedicated interrupt is generated (ITP.ipend[]) if unmasked in the interrupt mask and priority register (ITMP.mask[]).

## 8.3 Watchdog

The watchdog is a specific 32-bit timer (decrementer shared with Timer1 and Timer2).

Figure 8-3. Watchdog Block Diagram

The watchdog is accessible through a single watchdog register (WDG):

- the watchdog is always enabled
- the counter (WDG.cnt) is decremented each time the prescaler generates a tick pulse unless it has reached zero
- the WDOG\* signal is asserted when the counter expires at zero (no other internal event generated)
- the counter never underflows and shall be refreshed by directly reloading a value into the counter
- after reset, the watchdog counter is initialized to the maximum possible value<sup>1</sup>

Note: 1. Considering the prescaler is initialized to the minimum value after a reset (a division rate of 4), the watchdog will expire after  $(2^{32} - 1) \times 4$  cycles, unless later programmed otherwise.

The watchdog can be used to generate a system reset on expiration by directly connecting the WDOG\* open-drain output pin to the PROC\_RESET\* pin.

## 9. UART

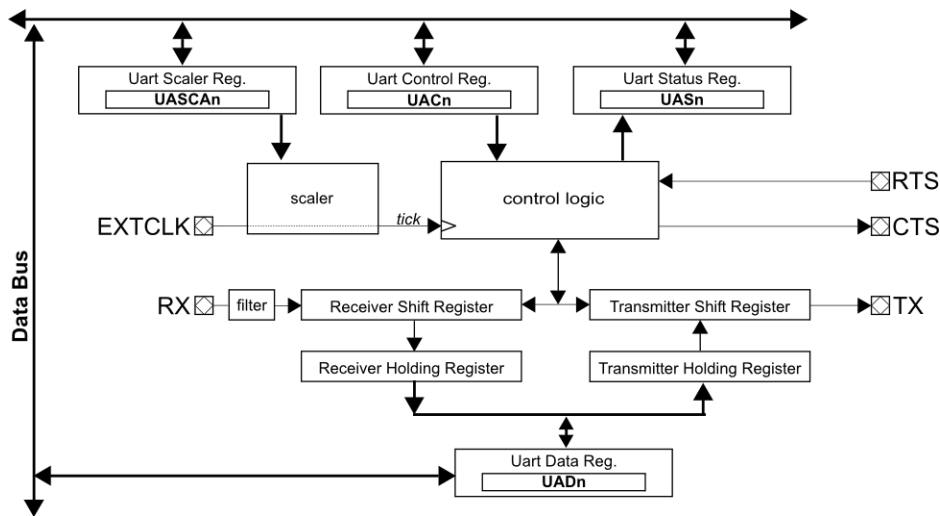

The Universal Asynchronous Receiver and Transmitter (UART) is a highly flexible serial communication module. The ATF697FF processor implements two uarts: UART1 and UART2. UARTs on the processor are defined as alternate functions of the general purpose interface (GPI).

### 9.1 Overview

Each UART *n* operates independently and is fully controlled by a set of 4 registers:

- a control register (UACn)
- a status register (UASn)
- a scaler register (UASCAn)
- a data register (UADn)

Figure 9-1. UART Block Diagram

#### 9.1.1 Data Frame

A data frame consists in a start bit, 8 data bits, an optional parity bit and a stop bit.

Figure 9-2. Data Frames

Data frame, no parity: 

Start	D0	D1	D2	D3	D4	D5	D6	D7	Stop
-------	----	----	----	----	----	----	----	----	------

Data frame with parity: 

Start	D0	D1	D2	D3	D4	D5	D6	D7	Parity	Stop
-------	----	----	----	----	----	----	----	----	--------	------

Parity in a data frame is controlled as follows:

- the parity can be enabled or disabled (UACn.pe)

- when enabled (UACn.pe = 1), the parity can be even or odd (UACn.ps)

When even (UACn.ps = 1), the parity bit is generated such as the number of 1s in the data and the parity is even. When odd (UACn.ps = 0), the parity bit is generated such as the number of 1s is odd.

## 9.1.2 Baud-Rate

The internal baud-rate generator requires a clock source to operate, which can either be internal or external (UACn.ec).

### 9.1.2.1 Internal Clock

When configured for internal clock (UACn.ec = 0), the UART baud-rate comes from a programmable 12-bits scaler controlled by a configuration register (UASCAn):

- the scaler is enabled only when the UART transmitter (UACn.te = 0) and/or the UART receiver (UACn.re = 0) are enabled
- when enabled (UACn.te = 1 and/or UACn.re = 1), the scaler counter is clocked by the system clock and decremented on each clock cycle
- the scaler counter is reloaded from the scaler reload register (UASCAn.rv) after it underflows and a UART tick is generated for the transmitter and the receiver (tick frequency is 8 times the desired baud-rate)

The following equations shall be used to calculate the scaler value or the baudrate value based on the clock frequency:

$$scaler_{rv} = \frac{sdclk_{freq}}{baudrate \times 8} - 1$$

$$baudrate = \frac{sdclk_{freq}}{8 \times (scaler_{rv} + 1)}$$

variable description:

- sdclkfreq: internal clock frequency
- baudrate: targeted/resulting baud rate
- scalerrv: resulting/targeted scaler reload value

### 9.1.3 External Clock

When configured for an external clock (UACn.ec = 1), the UART scaler is bypassed and GPIO[3] directly provides the UART tick to the transmitter and the receiver (tick frequency is 8 times the desired baud-rate).

The external clock frequency shall be 8 times the desired baud-rate.

When configured for an external clock source, the clock high and low time on GPIO[3] shall each be longer than the period of the internal system clock (so proper sampling is achieved).

### 9.1.4 Double Buffering

Each UART performs double-buffering (a holding register and a shift register) on the transmitter and the receiver to optimize the data transfer in both directions (no transmitter stopped waiting for reload, no data loss on receiver overrun).

### 9.1.5 Hardware Flow-Control

Each UART n can perform hardware flow-control to further optimize and secure data transfer in both directions:

- hardware flow-control can be enabled or disabled (UACn.fl)
- when enabled (UACn.fl = 1) together with the transmitter (UACn.te = 1), no new data transmit is initiated until the clear-to-send input pin (CTS<sub>n</sub>) is asserted (data transmission is not interrupted is deasserted in the middle of the transmission)
- when enabled (UACn.fl = 1) together with the receiver (UACn.re = 1), the request-to-send output pin (RTS<sub>n</sub>) is asserted as long as new data can be received

### 9.1.6 Noise Filtering

The serial input is shifted through an 8-bit filter which changes output only when all bits in the filter have the same value, effectively forming a low-pass filter with a cut-off frequency of 1/8 system clock.

## 9.2 Operation

### 9.2.1 Transmitter Operation

UART n transmitter is first configured as follows:

- the transmitter shall be enabled ( $UACn.te = 1$ )
- the transmitter serial-output pin (TXn) shall be enabled on the general-purpose interface by configuring the appropriate pin to output mode (GPIO[15] for UART1 and GPIO [11] for UART2)
- if flow-control is enabled ( $UACn.fl = 1$ ), the transmitter clear-to-send pin (CTS<sub>n</sub>) shall be enabled on the general-purpose interface by configuring the appropriate pin to input mode (GPIO[12] for UART1 and GPIO[8] for UART2)

When ready to transmit, data written to the transmitter holding register (UAD<sub>n</sub>.rtd) is transferred into the transmitter shift register and converted to a serial data frame on the transmitter serial output pin (TX<sub>n</sub>).

Following the transmission of the stop bit, the transmitter serial data output remains high and the transmitter shift register empty flag is asserted ( $UASn.ts = 1$ ) if no new data is available in the transmitter holding register.

Transmission resumes and the transmitter shift register empty flag is deasserted ( $UASn.ts = 0$ ) when new data is loaded in the transmitter holding register (UAD<sub>n</sub>.rtd).

### 9.2.2 Receiver Operation

UART n receiver is first configured as follows:

- the receiver shall be enabled ( $UACn.re = 1$ )
- the receiver serial-input pin (RX<sub>n</sub>) shall be enabled on the general-purpose interface by configuring the appropriate pin (GPIO[14] for UART1 and GPIO[10] for UART2) to input mode
- if flow-control is enabled ( $UACn.fl = 1$ ), the receiver request-to-send pin (RTS<sub>n</sub>) shall be enabled on the general-purpose interface by configuring the appropriate pin (GPIO[13] for UART1 and GPIO[9] for UART2) to output mode

The receiver constantly looks for the high to low transition of a start bit on the receiver serial data input pin (RX<sub>n</sub>). If a transition is detected, the state of the serial input is sampled a half-bit later for confirmation and a valid start bit is assumed if the serial input is still low, otherwise the search for a valid start bit continues.

Then the receiver continues to sample the serial input at one bit time intervals (at the theoretical centre of the bit) until the proper number of data bits and optionally the parity bit have been assembled and one stop bit has been detected.

The data is transferred to the receiver holding register and the data ready flag is asserted ( $UASn.dr = 1$ ) by the end of the reception if no error was detected. Otherwise, no data ready flag is asserted and the error is reported in the appropriate flag:

- a parity error ( $UASn.pe = 1$ ) occurs when parity is enabled ( $UACn.pe = 1$ ) and the received parity does not match the selected parity configuration ( $UACn.ps$ )
- a framing error ( $UASn.fe = 1$ ) occurs when the received stop bit is a 0 rather than a 1
- a break received ( $UASn.br = 1$ ) occurs when the received data and the stop bit are all 0s
- an overrun error ( $UASn.ov = 1$ ) occurs when the holding register already contains an un-read data

**Caution:** The errors bits are never cleared by the receiver and shall be cleared in software so new errors can later be detected.

Reading the UART data register (UAD<sub>n</sub>.rtd) empties the receiver holding register and deasserts the data ready flag ( $UASn.dr = 0$ ).

### 9.2.3 Interrupt Generation

Each UART n can be configured to generate an interrupt each time a byte has been received and/or is about to be sent:

- transmitter interrupt can be enabled/disabled (UACn.ti)
- receiver interrupt can be enabled/disabled (UACn.ri)

Note: When enabled (UACn.ti = 1), the transmitter issues an interrupt when the transmitter holding register is emptied (transfer into the transmitter shift register for sending).

When enabled (UACn.ri = 1), the receiver issues an interrupt after serial data has been received (data made ready into the receiver holding register or errors reported).

The interrupt is made effective (ITP.ipend[3] for UART1 and ITP.ipend[2] for UART2) only if unmasked in the interrupt mask and priority register (ITP.imask[3] for UART1 and ITP.imask[2] for UART2).

### 9.2.4 Loop-Back Mode

Each UART n can be configured in loop-back mode (UACn.lb) for testing purpose.

When enabled<sup>1</sup>(UACn.lb = 1), the transmitter serial-output<sup>2</sup> is internally connected to the receiver serial-input<sup>3</sup> and the receiver request-to send output<sup>4</sup> is internally connected to the transmitter clear-to-send input<sup>5</sup>.

Note: 1. In loop-back mode, the corresponding general-purpose I/O pins need not be configured since all the connections are directly performed internally.

Note: 2. If the transmitter is enabled and the corresponding general purpose I/O pin (TXn) is configured as an output, a constant 1 is output instead of the programmed I/O data.

Note: 3. No parity error or framing error or break received can be generated since the transmitter and the receiver both share the same parity and baud-rate configuration.

Note: 4. If flow-control is enabled and the corresponding general purpose I/O pin (RTSn) is configured as an output, a constant 1 is output instead of the programmed I/O data.

Note: 5. No overrun error can be generated if flow-control is enabled.

## 10. GPIO

### 10.1 Processor General Purpose Interface

The general purpose interface (GPI) consists in a partially bit-wise programmable 32-bit I/O port with alternate facilities.

#### 10.1.1 GPI as a 32-bit I/O Port

The port is split in two parts the lower 16-bits are accessible via the GPIO[15:0] pins while the upper 16-bits are accessible via D[15:0] and can only be used when all the external memory areas (ROM, SRAM and I/O) are in 8-bit mode (see “8-bit PROM and SRAM Access”). If the SDRAM controller is enabled, the upper 16-bits cannot be used.

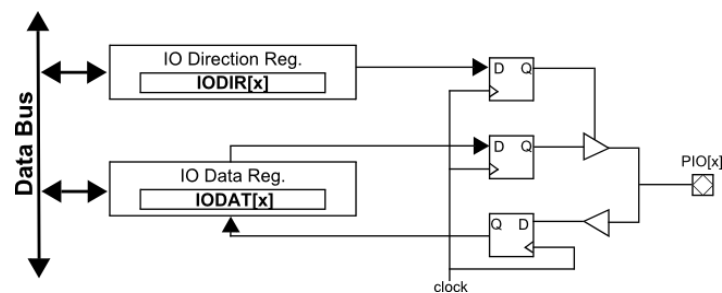

##### 10.1.1.1 Lower 16-bits Operation

The lower 16 bits of the I/O port can be individually programmed as output or input, they are accessible through GPIO[15:0].

Each pin  $n$  in GPIO[15:0] is controlled by two registers (IODIR and IODAT):

- the pin can be configured as an input or an output (IODIR.piodir[n])
- when configured as an input (IODIR.piodir[n] = 0), the bit value in the data register (IODAT.piodat[n]) continuously reflects the pin value
- when configured as an output (IODIR.piodir[n] = 1), the bit value in the data register (IODAT.piodat[n]) is continuously output on the pin

Figure 10-1. I/O Port Block Diagram GPIO[15:0]

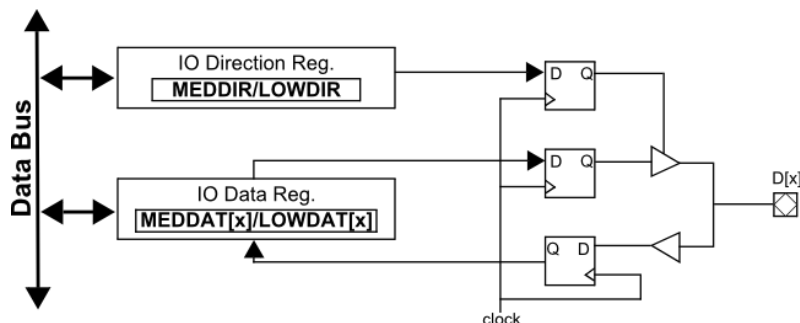

##### 10.1.1.2 Upper 16-bits Operation

The upper 16 bits of the I/O port can only be configured as outputs or inputs on a byte basis. D[15:8] is referenced as the medium byte while D[7:0] is referenced as the lower byte.

Each byte in D[15:0] is controlled by 2 registers (IODIR and IODAT):

- the whole byte can be configured as an input or an output (IODIR.meddir and IODIR.lowdir)
- when configured as an input (IODIR.meddir = 0 and/or IODIR.lowdir = 0), the byte value in the data register (IODAT.meddat and IODAT.lowdat) continuously reflects the corresponding pins byte value
- when configured as an output (IODIR.meddir = 1 and/or IODIR.lowdir = 1), the byte value in the data register (IODAT.meddat and IODAT.lowdat) is continuously output on the corresponding byte pins

Figure 10-2. I/O Port Block Diagram D[15:0]

### 10.1.2 GPI Alternate Functions

Most GPI pins have alternate functions in addition to being general I/O. Facilities like serial communication link, interrupt input and configuration are made available through these functions. The following table summarizes the assignment of the alternate functions.

Table 10-1. GPI alternate functions

GPI port pin	Alternate function
GPIO[15]	TXD1 UART1 transmitter data <sup>13</sup>
GPIO[14]	RXD1 UART1 receiver data <sup>24</sup>
GPIO[13]	RTS1 UART1 request-to-send <sup>145</sup>
GPIO[12]	CTS1 UART1 clear-to-send <sup>235</sup>
GPIO[11]	TXD2 UART2 transmitter data <sup>13</sup>
GPIO[10]	RXD2 UART2 receiver data <sup>24</sup>
GPIO[9]	RTS2 UART2 request-to-send <sup>145</sup>
GPIO[8]	CTS2 UART2 clear-to-send <sup>235</sup>
GPIO[3]	EXTCLK Use as alternative UART clock <sup>2</sup>
GPIO[2]	PROM EDAC enable Enable EDAC protection on boot <sup>6</sup>
GPIO[1:0]	PROM width Defines PROM data bus width on boot <sup>6</sup>

Note: 1. The corresponding GPI port pin shall be configured in output mode so the UART output signal is effective on that pin.

Note: 2. The corresponding GPI port pin shall be configured in input mode so the UART input signal is effective on that pin.

Note: 3. The corresponding UART transmitter shall be enabled

Note: 4. The corresponding UART receiver shall be enabled

Note: 5. Flow-control shall be enabled on the corresponding UART

Note: 6. Pin is sampled during reset and can be used as a general purpose I/O pin after reset

In addition to these alternate functions, each GPI interface pin can be configured as an interrupt input to catch interrupts from external devices. Up to eight interrupts can be configured on the GPI interface by programming the I/O interrupt registers (IOIT1 and IOIT2).

For a detailed description about the external interrupts configuration, please refer to the “Traps and Interrupts” section.

The GPIO0 to GPIO7 are shared internally between the processor and the reconfigurable unit and are also connected externally.

The GPIO8 to GPIO15 are only connected to the processor.

**Caution:** Warning: The shared IOs have to be correctly configured to avoid signal reflexions and damages on the IO of the ATF697FF component. In particular, several outputs on the same IO should not be configured in output at the same time.

## 10.2 Reconfigurable Unit General Purpose Interface

The ATF697FF reconfigurable unit provides a full set of highly configurable general purpose IOs.

For some of the FPGA IOs, the general purpose function of the IO is multiplexed with other functions such as mentioned in the Pin Description section. Please refer to the Pin Description section for details on the multiplexed functions of each IO.

It must be noted that while the configuration logic controls dual-use I/O pins during the **configuration download** lifephase, the configuration logic does not control the general purpose configuration.

**Figure 10-3. Dual Use I/O principle**

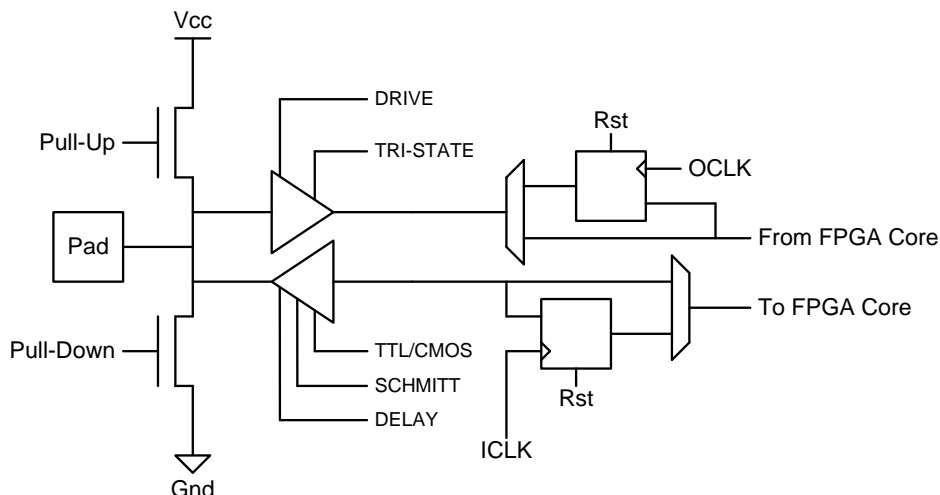

**Caution:** The user must be cautioned to avoid possible system problems with the use of dual-use I/O pins. For example, turning off the internal pull-up resistor for the open drain INIT pin would not apply the weak High required of an open drain driver. Conversely, disabling the pull-up and enabling the pull-down of the HDC pin might be a good idea, since the user may then actually see the pin go Low at the end of configuration.

Dual-use pins share input buffers. It should be noted that even when the configuration has claimed a pin for its own purposes, the user input buffer is still fully functional. This implies that any user logic tied to the input buffers of the pins in question will remain operational.

Each programmable I/O can be configured as input, output or bi-directional. When configured as input an optional Schmitt trigger can be enabled on the I/O. When configured as output, optional PCI compatibility can be enabled. It is also possible to select the output buffer drive to optimize the performance of an interface in the application. In addition, the ATF697FF reconfigurable unit provides pull-up and pull-down capability on each I/O.

Here is an overview of the IO structure.

**Figure 10-4. ATF697FF reconfigurable unit I/O structure**

The following section presents all the possible configurations available for a programmable I/O.

### 10.2.1 Direction Configuration

Each of the general purpose IO can be individually configured in one of the following direction:

- Input,
- Output,
- Bidirectional.

### 10.2.2 Pull-up/Pull-down

Each pad has a programmable pull-up and pull-down attached to it. This supplies a weak “1” or “0” level to the pad pin. When all other drivers are off, this control will dictate the signal level of the pad pin.

The pull-up and pull-down configuration is independent from any other configuration of the pad. The consequence is that it is possible to use the pull-up/pull-down configuration together with any of the other IO configuration.

The pull-up/pull-down configuration is available both for inputs and outputs.

**Caution:** By default, when an IO is not configured in the application bitstream of the FPGA, the IO pull-up is activated

### 10.2.3 Output Configuration

The ATF697FF reconfigurable unit proposes a full set of configuration for the output management. Here are the descriptions for all the available settings.

#### 10.2.3.1 Standard Configuration

In standard configuration, the IOs in output mode support a tri-state configuration. It is then possible to drive

- low level (logical 0)
- high level (logical 1)
- high impedance (logical Z)

#### 10.2.3.2 Open Source

When configured in open source mode the IOs configured in output can only support

- high level (logical 1)
- high impedance (logical Z)

Note: In such a configuration, it is possible to drive a weak “0” by using the internal pull-down capability of the driver

### 10.2.3.3 Open Drain

When configured in open drain mode the IOs configured in output can only support

- low level (logical 0)
- high impedance (logical Z)

Note: In such a configuration, it is possible to drive a weak “1” by using the internal pull-up capability of the driver

### 10.2.3.4 Output drive

On the ATF697FF reconfigurable unit, the output drive of each I/O configured in output is programmable. The drive capability is dependent upon the settings of the drive parameter inside the bitstream of the FPGA (FAST, MEDIUM and SLOW).

Three values are available for configuration of the drive for each output:

- FAST

When configured in FAST mode, the output buffer is capable to drive a high level of current. Such drive capability leads to fast slew rate whatever is the load on the pin

Note: In this mode, the current drive is compliant with the PCI specification.

- MEDIUM

When configured in MEDIUM mode, the output buffer is capable to drive an intermediate level of current.

- SLOW

When configured in SLOW mode, the output buffer is capable to drive a small level of current. Such drive capability leads to slow slew rate as soon as the load is important. SLOW configuration yields to standard buffer usage.

**Table 10-2. Drive Capability for VCC = 3.3V**

VCC=3.3V Config	I <sub>OH</sub> (mA)		I <sub>OL</sub> (mA)	
	Worst Case	Typical	Worst Case	Typical
SLOW	4	8	4	9
MEDIUM	10	17	10	23
FAST	14	22	14	28

**Caution:** When no modification is performed by the user on the IDS software, the default configuration of the drive for the I/Os is **FAST**.

## 10.2.4 Input Configuration

### 10.2.4.1 Schmitt

A Schmitt trigger circuit can be enabled on the inputs. The Schmitt trigger is a regenerative comparator circuit that adds 0.8V hysteresis to the input. This effectively improves the rise and fall times (leading and trailing edges) of the incoming signal and can be useful for filtering out noise.

### 10.2.4.2 Delays

The input buffer can be programmed to include four different intrinsic delays as specified in the AC timing characteristics. This feature is useful for meeting data hold requirements for the input signal.

### 10.3 LVDS Interfaces

The ATF697FF provides 16 pairs of LVDS IOs that comply with the **EIA-644 standard requirements**.

The basic LVDS interface consists in a single differential link interconnected between a transmitter and a receiver. Such a link requires a termination resistor on the receiver side to allow high frequency transfer usage. The nominal resistor value for the termination resistor 100 ohms.

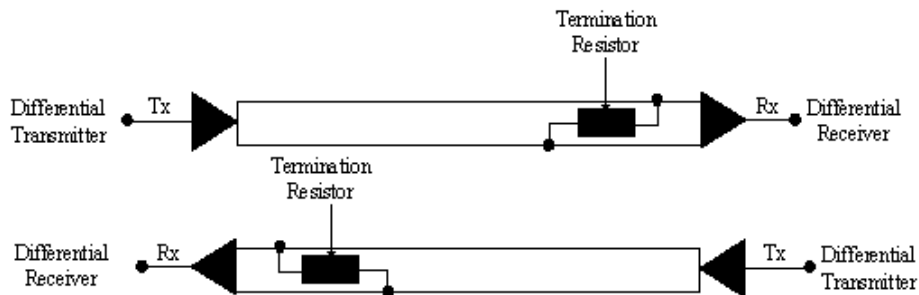

**Figure 10-5. LVDS basic interface**

The LVDS I/Os embedded on the ATF697FF are composed of 4 LVDS transceiver (Tx) pairs, 4 receivers (Rx) pairs together with the reference voltages (LVDS\_REF\_A and LVDS\_REF\_B). that must be connected to an accurate 1.25V voltage to give references to the transceivers and to the receivers. They are spread in 2 clusters, each one consisting in

- 2x transceivers
- 2x receivers
- 1x reference voltage.

**Figure 10-6. LVDS bidirectional communication principle**

The LVDS\_REF\_B is the reference voltage for LVDSB1 and LVDSB2.

The LVDS\_REF\_A is the reference voltage for LVDSA1 and LVDSA2.

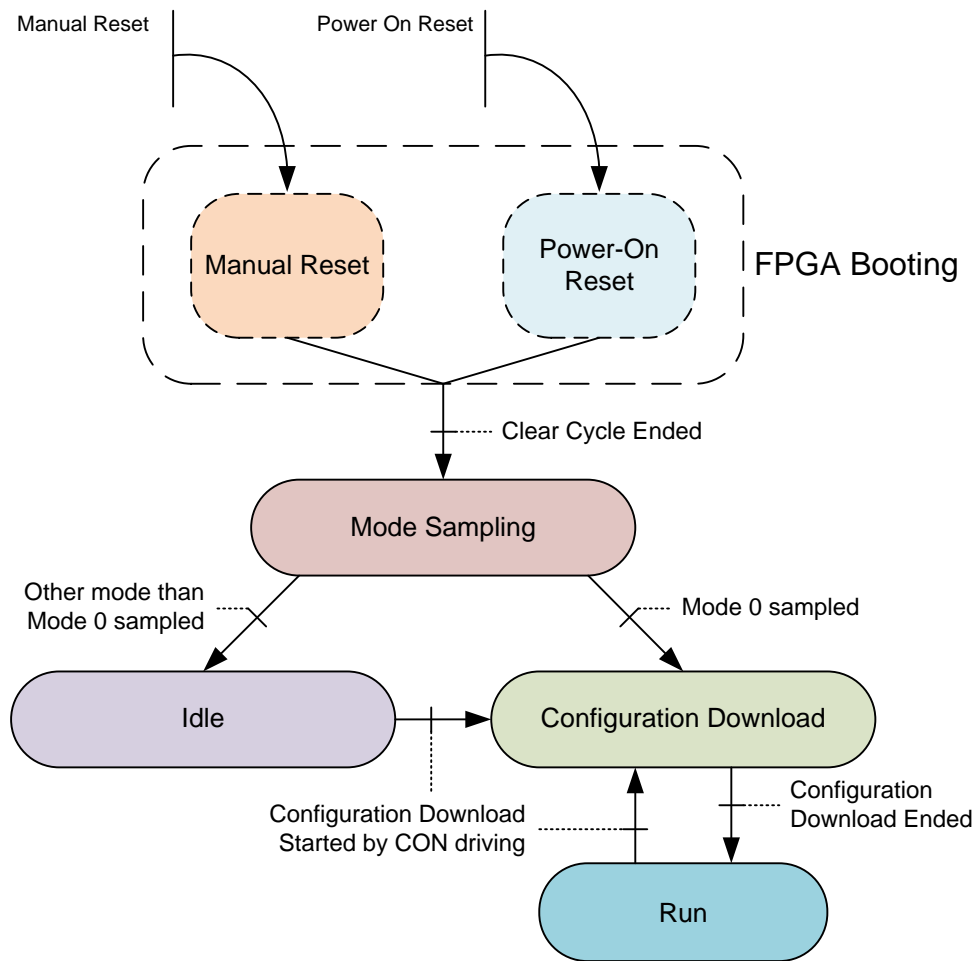

## 11. ATF697FF reconfigurable unit:

### 11.1 Operating Modes / Lifephases

The ATF697FF reconfigurable unit behaves following a deterministic life cycle. The complete life cycle of the FPGA refers to an optimized number of lifephases that are summarized in the following life cycle.

Figure 11-1. ATF697FF reconfigurable unit: Life Cycle diagram

For some of the FPGA IOs, the general purpose function of the IO is multiplexed with other functions such as configuration function, clock function... as mentioned in the Pin Description section. For the multiplexed IOs, the function that is activated at a given time is directly dependent from the lifephase currently executed.

In each of the lifephase description here after, the multiplexed IO function availability is presented.

## 11.1.1 Power-On Reset

### 11.1.1.1 Description

This **Power-On Reset** lifephase occurs when power is first applied to the part. The FPGA initiates a complete clearing of its internal configuration SRAM (configuration clear cycle) prior entering in Mode Sampling lifephase. Before performing the configuration clear cycle, the power supply is sensed until the threshold voltage is reached then the internal logic activates.

In order to ensure the power supply stability to erase properly each configuration SRAM point, the ATF697FF reconfigurable unit loops and perform configuration clear cycle during hardcoded silicon timing.

### 11.1.1.2 Pin Function Availability

Table 11-1. Pin Function during Power-On Reset

ATF697FF reconfigurable unit Pin names	Lifephase = Power-On Reset
FPGA_RESET*	[CFG]
M0, M1, M2	[CFG]
IO303_INIT	[CFG]

IO225_OTS*	[GPIO] <sup>1</sup>
IOx	[GPIO] <sup>1</sup>
IOx_GCKy	[GPIO] <sup>1</sup>
IOx_FCKy	[GPIO] <sup>1</sup>

Notes: 1. During Power-On Reset lifephase, the ATF697FF reconfigurable unit configuration SRAM is not configured, all GPIO functions remain in input with pull-up (by default).

## 11.1.2 Manual Reset

### 11.1.2.1 Description

This **Manual Reset** lifephase occurs when the RESET function is activated by the user. The FPGA initiates a configuration clear cycle prior entering Mode Sampling lifephase when RESET function is released. As power supplies are already stable, the configuration clear cycle is done once and takes a time which depends of the silicon intrinsic speed and the size of the FPGA matrix.

### 11.1.2.2 Pin Function Availability

Table 11-2. Pin Function during Manual Reset

ATF697FF reconfigurable unit Pin names	Lifephase = Manual Reset
FPGA_RESET*	[CFG]

IOx	[GPIO] <sup>1</sup>
IOx_GCKy	[GPIO] <sup>1</sup>
IOx_FCKy	[GPIO] <sup>1</sup>

Notes: 1. During Manual Reset lifephase, the ATF697FF reconfigurable unit configuration SRAM is not configured, all GPIO functions remain in input with pull-up (by default).

### 11.1.3 Mode Sampling

#### 11.1.3.1 Description

This **Mode Sampling** lifephase is entered each time the FPGA has performed either Power-On-Reset or Manual Reset lifephases. In this state, the FPGA starts to drive the configuration logic interface appropriately and samples the mode pins. Depending on the values sampled through the mode pins, the ATF697FF reconfigurable unit can be configured in the following modes:

- Mode 0: Master Serial Mode
- Mode 1: Slave Serial Mode with the use of a chip select input
- Mode 7: Slave Serial Mode

These modes directly affect the **Configuration Download** lifephase and lead to five different contexts for these these lifephase.

#### 11.1.3.2 Pin Function Availability

Table 11-3. Pin Function Mode Sampling

ATF697FF reconfigurable unit Pin names	Lifephase = Mode Sampling
FPGA_RESET*	[CFG]
M0, M1, M2	[CFG]
IO303_INIT	[CFG]
CON	[CFG]
CCLK	[CFG]
IO713_D0	[CFG]
IO259_LDC	[CFG]

IO225_OTS*	[GPIO] <sup>1</sup>
IOx	[GPIO] <sup>1</sup>
IOx_GCKy	[GPIO] <sup>1</sup>
IOx_FCKy	[GPIO] <sup>1</sup>

Notes: 1. During Manual Reset lifephase, the ATF697FF reconfigurable unit configuration SRAM is not configured, all GPIO functions remained in input with pull-up (by default).

## 11.1.4 Idle

### 11.1.4.1 Description

This *Idle* lifephase is entered when the FPGA does no activities. The FPGA enters in this state after Mode Sampling state when configured in slave mode. In Idle state, the configuration logic interface is released.

### 11.1.4.2 Pin Function Availability

Table 11-4. Pin Function during Idle

ATF697FF reconfigurable unit Pin names	Lifephase = Idle
FPGA_RESET*	[CFG]
M0, M1, M2	[CFG]
IO303_INIT	[GPIO] <sup>1</sup>
CON	[CFG]
CCLK	[CFG]

IO655_CHECK*	[GPIO] <sup>1</sup>
IO225_OTS*	[GPIO] <sup>1</sup>
IOx	[GPIO] <sup>1</sup>
IOx_GCKy	[GPIO] <sup>1</sup>
IOx_FCKy	[GPIO] <sup>1</sup>

Notes: 1. During Idle lifephase, the ATF697FF reconfigurable unit configuration SRAM is not configured, all GPIO functions remained in input with pull-up (by default).

## 11.1.5 Configuration Download

### 11.1.5.1 Description

This **Configuration Download** lifephase from a system point of view is a sequence of event managed by the FPGA in order to ensure the configuration of its internal SRAM. This lifephase is entered after Mode Sampling state when configured in master mode. Else the FPGA enters this lifephase after Idle state when an external master triggers the start of configuration download (could be either in slave or master mode).

Five different contexts are defined for this lifephase regarding the mode sampled in Mode Sampling.

### 11.1.5.2 Pin Function Availability

**Table 11-5. Pin Function during Configuration Download**

ATF697FF reconfigurable unit Pin names	Lifephase = Configuration Download		
	Mode 0	Mode 1	Mode 7
FPGA_RESET*	[CFG]	[CFG]	[CFG]
M0, M1, M2	[CFG]	[CFG]	[CFG]
IO303_INIT	[CFG]	[CFG]	[CFG]
CON	[CFG]	[CFG]	[CFG]
CCLK	[CFG]	[CFG]	[CFG]
IO713_D0	[CFG]	[CFG]	[CFG]
IO259_LDC	[CFG]	[CFG]	[CFG]
IO265_HDC	[CFG]	[CFG]	[CFG]
IO547_CS0	[GPIO] <sup>1</sup>	[CFG]	[GPIO] <sup>1</sup>
IO720_GCK6_CSOUT	[CFG] or [GPIO] <sup>2</sup>	[CFG] or [GPIO] <sup>3</sup>	[CFG] or [GPIO] <sup>3</sup>
IO655_CHECK*	[CFG] or [GPIO] <sup>2</sup>	[CFG] or [GPIO] <sup>3</sup>	[CFG] or [GPIO] <sup>3</sup>
IO225_OTS*	[CFG] or [GPIO] <sup>2</sup>	[CFG] or [GPIO] <sup>3</sup>	[CFG] or [GPIO] <sup>3</sup>
IOx	[GPIO] <sup>1</sup>	[GPIO] <sup>1</sup>	[GPIO] <sup>1</sup>
IOx_GCKy	[GPIO] <sup>1</sup>	[GPIO] <sup>1</sup>	[GPIO] <sup>1</sup>
IOx_FCKy	[GPIO] <sup>1</sup>	[GPIO] <sup>1</sup>	[GPIO] <sup>1</sup>

Note: 1. If entering Configuration lifephase from Idle then the ATF697FF reconfigurable unit configuration SRAM is not configured: all GPIO functions remained in input with pull-up (by default). Else if entering Configuration lifephase from Run then the ATF697FF reconfigurable unit configuration SRAM is already configured: all GPIO functions remained in their configured state.

Note: 2. IO720\_GCK6\_CSOUT, IO655\_CHECK\* and IO225\_OTS\* are configured in [CFG] function during configuration download if the appropriate function is activated (respectively cascading mode, CHECK function, Output Tri-State) (Refer to bitstream configuration for more details)

Note: 3. IO720\_GCK6\_CSOUT, IO655\_CHECK\* & IO225\_OTS\* are configured in [CFG] function during configuration download if the appropriate function is activated (respectively cascading mode, CHECK function, Output tri state).

## 11.1.6 Run

### 11.1.6.1 Description

The **Run** lifephase is the operating state of the FPGA and is design dependent. It means that in this lifephase, the loaded design runs and its own lifephases are taken into account.

### 11.1.6.2 Pin Function Availability

Table 11-6. Pin Function during Run

ATF697FF reconfigurable unit Pin names	Lifephase = Run			
	Nominal	OTS	CSIC	Free Run oscillator
FPGA_RESET*	[CFG]	[CFG]	[CFG]	[CFG]
M0, M1, M2	[CFG]	[CFG]	[CFG]	[CFG]
IO303_INIT	[GPIO]	[GPIO]	[CFG]	[GPIO]
CON	[CFG]	[CFG]	[CFG]	[CFG]

IO720_GCK6_CSOUT	[GPIO]or[CLOCK]	[GPIO]or[CLOCK]	[GPIO]or[CLOCK]	[GPIO]or[CLOCK]
IO655_CHECK*	[GPIO]	[GPIO]	[GPIO]	[GPIO]
IO225_OTS*	[GPIO]	[CFG]	[GPIO]	[GPIO]
IOx	[GPIO]	[GPIO]	[GPIO]	[GPIO]
IOx_GCKy	[GPIO]or[CLOCK]	[GPIO]or[CLOCK]	[GPIO]or[CLOCK]	[GPIO]or[CLOCK]
IOx_FCKy	[GPIO]or[CLOCK]	[GPIO]or[CLOCK]	[GPIO]or[CLOCK]	[GPIO]or[CLOCK]

Notes: 1. When using the Free Run Oscillator in mode 0 only (refer to **Register** section about CR13), the CCLK pin is output as clock signal. The user shall take care of this at system level.

## 11.2 Configuration Download

Configuration is the process by which a design is loaded into an ATF697FF reconfigurable unit. The ATF697FF reconfigurable unit is a SRAM based FPGA, this leads to an unlimited reprogrammability capability.

It is possible to configure either the entire device or only a portion of the device. Sections can be configured while others continue to operate undisturbed. The architecture of the ATF697FF reconfigurable unit leads to a maximum bitstream size of 2.5M bits. It is possible to store configuration bit-streams of the ATF697FF reconfigurable unit in one single 4Mbit EEPROM.

Full configuration takes only milliseconds. Partial configuration takes even less time and is a function of design density.

Configuration data is transferred to the device in one of the five modes supported by the ATF697FF reconfigurable unit. Three dedicated input pins M0, M1 and M2 are used to determine the configuration mode.

The ATF697FF reconfigurable unit supports an auto-configuring Master serial mode and two Slave serial modes.

The following table summarizes the ATF697FF reconfigurable unit configuration modes:

**Table 11-7. Configuration Mode Overview**

Configuration Download Mode						
Mode	Description	M2	M1	M0	CCLK	Data
0	Master serial	0	0	0	Output	Serial
1	Slave serial	0	0	1	Input	Serial
7	Slave serial	1	1	1	Input	Serial

## 11.2.1 Serial Configuration

### 11.2.1.1 Bitstream Structure

The configuration bitstream for the ATF697FF reconfigurable unit consists in a flexible structured set of data that allows configuration of the FPGA structure but also protection of the configuration data link.

The following table shows the global structure of a bitstream for ATF697FF reconfigurable unit.

**Table 11-8. ATF697FF reconfigurable unit Bitstream structure**

Bitstream decomposition		
Description	Sub Zone	Zone Size (byte)
Null byte		1
Preamble		1
Configuration Registers	CR3	4
	CR2	
	CR1	
	CR0	
Number of Windows		2
Data Window1	Start Address	3
	Stop Address	3
	Data	Data Size
Data Window2	Start Address	3
	Stop Address	3
	Data	Data Size
Data WindowN <sup>1</sup>	Start Address	3
	Stop Address	3
	Data	Data Size
Checksum	Start Address	3
	Stop Address	3
	Data	1
Recurrent Checksum <sup>2</sup>	Start Address	3
	Stop Address	3
	Data	1
Postamble		1

Note: 1. N could be at least 1, at maximum 65535.

Note: 2. Optional: the Recurrent Cheksum is integrated to the bitstream by IDS by activating the appropriate option (CR8 in configuration Register)

## Null Byte

The “null byte” is always present in the ATF697FF reconfigurable unit bitstreams. It is used by the configuration download state machine as a download protocol start indicator.

Its value is always “00000000”.

## Preamble

The “preamble” is always present in the ATF697FF reconfigurable unit bitstreams. It is used by the configuration download state machine for verifying that the bitstream proposed on the configuration link is well suited for ATF697FF reconfigurable unit FPGA type.

Its value is always set to “10110111”

## Configuration Register

The configuration register is made of four eight-bit wide registers used to configure the FPGA embedded functions. These register allows configuration of FPGA functions such as clock configuration, IO configuration... options. For the details on the configuration register options content, please refer to the **Registers** section.

The configuration registers are always present in the ATF697FF reconfigurable unit bitstreams.

## Number of Windows

The number of windows section provides the exact number of windows used in the bitstream to be downloaded. Its value is computed by the FPGA Integrated Design System development tool and is fully dependent from the content of the FPGA application.

The number of windows is always present in an ATF697FF reconfigurable unit bitstream.

## Data Window

The windows are the zones used to configure the different internal applicative structures of the FPGA. Each window is made of the following elements:

- A “Start Address” which is a 24 bits word (3 bytes). It is used to identify the starting point of the FPGA configuration SRAM mapping to be written
- A “Stop Address” which is a 24 bits word (3 bytes). It is used to delimit the end of the window, thus defining the number of data to be written in the configuration SRAM
- The “Data” section which contains the configuration data for the configuration memory itself. It is fully dependent upon the application being downloaded.

The ATF697FF bitstream always embeds a minimum of one data windows.

## Checksum Window

The FPGA Integrated Design System development tool calculates a checksum for each generated bitstream in order to provide the capability to secure the transfer of the data during configuration download. The checksum generated is one byte computed by data accumulation over the configuration registers data and the data of all the windows that precede the checksum window.

The checksum window is used to store this checksum into the FPGA at a defined location. That is why the checksum window is made of:

- A “Start Address” which is a 24 bits word (3 bytes). This address defines the location where the checksum will be written in the FPGA.

- A “Stop Address” which is a 24 bits word (3 bytes) to delimit the end of the window,
- The “Checksum Data”

The checksum window is always present in an ATF697FF bitstream.

## Recurrent Checksum

The FPGA Integrated Design System development tool is capable to calculate a recurrent checksum for each generated bitstream. The recurrent checksum is different from the simple checksum. It is used for self integrity checking. The recurrent checksum is computed by data accumulation over the configuration registers data and the data of all the windows that precede the recurrent checksum window.

The “Recurrent Checksum” window is made of the following elements:

- The “Start Address” which is a 24 bits word (3 bytes) to access the Recurrent Checksum location in the FPGA
- The “Stop Address” which is a 24 bits word (3 bytes) to delimit the end of the window
- The “Recurrent Checksum Data”

The recurrent checksum window is optional. It is only available when the recurrent checksum function is activated in the bitstream. For details on the recurrent checksum function usage, please refer to the **Self Integrity Checker function** section.

## Postamble

The “postamble” is always present in the ATF697FF reconfigurable unit bitstreams. It is used by the configuration download state machine as a download protocol stop indicator indicating the end of the transfer.

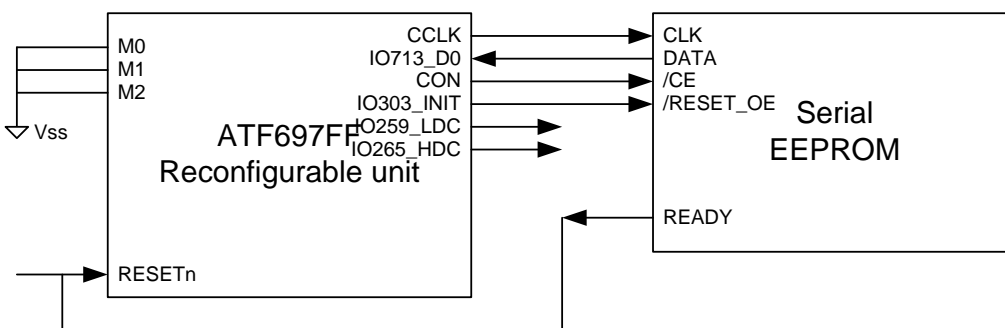

Its value is always “10110111”.

## 11.2.2 Master Mode – Mode 0

Mode 0 is a master mode. The Master Mode is auto-configuring; that is, after power-on-reset (POR) and the clearing of configuration memory, it self-initiates configuration. The Master Mode uses an internal oscillator to provide CCLK for clocking the external EEPROMs (configurators) which contain the configuration data. CCLK also drives the downstream devices (Slaves) in the configuration cascade chain. Master Serial Mode clocks and receives data from an EEPROM Serial Configuration Memory. After auto-configuration is complete, re-configuration can be initiated manually by the user.

In this mode, the ATF697FF reconfigurable unit is coupled to a serial EEPROM and managed automatically the whole configuration download phase. The automatic configuration download always starts after a Power-On reset or a Manual Reset. The following synoptic shows the required interface to be used for automatic configuration download purpose in mode 0.

**Figure 11-2. ATF697FF reconfigurable unit automatic configuration download in mode 0**

### 11.2.2.1 Configuration Download from Power-On Reset in mode 0

The chronogram described here after presents the sequence of ATF697FF reconfigurable unit from a **Power-On Reset** until **Run**. This is the global overview of ATF697FF reconfigurable unit automatic configuration download after a Power-On Reset.

**Figure 11-3. ATF697FF reconfigurable unit Configuration Download from Power-On Reset**

- Notes:
1. This line shows the different lifephase viewable in life cycle diagram described in **OperatingModes / Lifephases** section,
  2. “Rising” means here the rising of power supplies line,
  3. “CCE” means Clear Cycle End.

**[Power-On-Reset]:** During the Power-On Reset lifephase, the ATF697FF reconfigurable unit starts to drive the signal regarding the configuration download interfaces as defined below. The end of this lifephase is marked by the rising edge of IO303\_INIT pin:

- M0, M1, M2. these signals are inputs and not used,
- CCLK: this signal is internally pulled-up,
- IO713\_D0: this signal is internally pulled-up,
- CON: this signal is driven to a low logic level,
- IO303\_INIT: this signal is internally pulled-up until the end of the Clear Cycle operation (CCE). At this time, IO303\_INIT is driven to a low logic level during approximately 1 us,
- IO259\_LDC: the Low During Configuration is driven to a low logic level,
- IO265\_HDC: the High During Configuration is driven to a high logic level,
- FPGA\_RESET\* : this signal is an input which has no effect during the Power-On Reset lifephase.

**[Mode Sampling]:** During the Mode Sampling lifephase, the ATF697FF reconfigurable unit continues to drive the signal regarding configuration download interfaces. In addition, Mode Pins (M0, M1, M2) are sensed:

- M0, M1, M2. these signals are inputs and sensed to determine the used mode. If mode 0 is sampled (as shown in the figure above), the automatic configuration download starts.
- CCLK: this signal is internally pulled-up,

- IO713\_D0: this signal takes the value output by the EEPROM (first bit of the EEPROM),
- CON: this signal is driven to a low logic level,
- IO303\_INIT: this signal is internally pulled-up,
- IO259\_LDC: the Low During Configuration is driven to a low logic level,
- IO265\_HDC: the High During Configuration is driven to a high logic level,
- FPGA\_RESET\* : this signal is an input which immediately reset the configuration logic to a Manual Reset lifephase.

**[Configuration Download]:** During the Configuration Download lifephase, the ATF697FF reconfigurable unit continues to drive the signal regarding configuration download interfaces, this lifephase starts when CCLK pin is output:

- M0, M1, M2. these signals remain inputs and are not used anymore,
- CCLK: this signal is output as clock source for the serial EEPROM memory. At each rising edge of CCLK, the EEPROM memory outputs a new bit while the ATF697FF senses the previous bit. By default, the CCLK frequency toggles at a frequency of approximately 900 KHz.
- IO713\_D0: this signal is sampled by the FPGA at each rising edge of CCLK. It is the DATA output of the EEPROM memory,
- CON: this signal is driven to a low logic level,
- IO303\_INIT: this signal is internally pulled-up and is used as an error monitoring pin. Refer to **Data Link Protection** section for serial configuration,
- IO259\_LDC: the Low During Configuration is driven to a low logic level,
- IO265\_HDC: the High During Configuration is driven to a high logic level,
- FPGA\_RESET\* : this signal is an input which immediately reset the configuration logic to a Manual Reset lifephase.

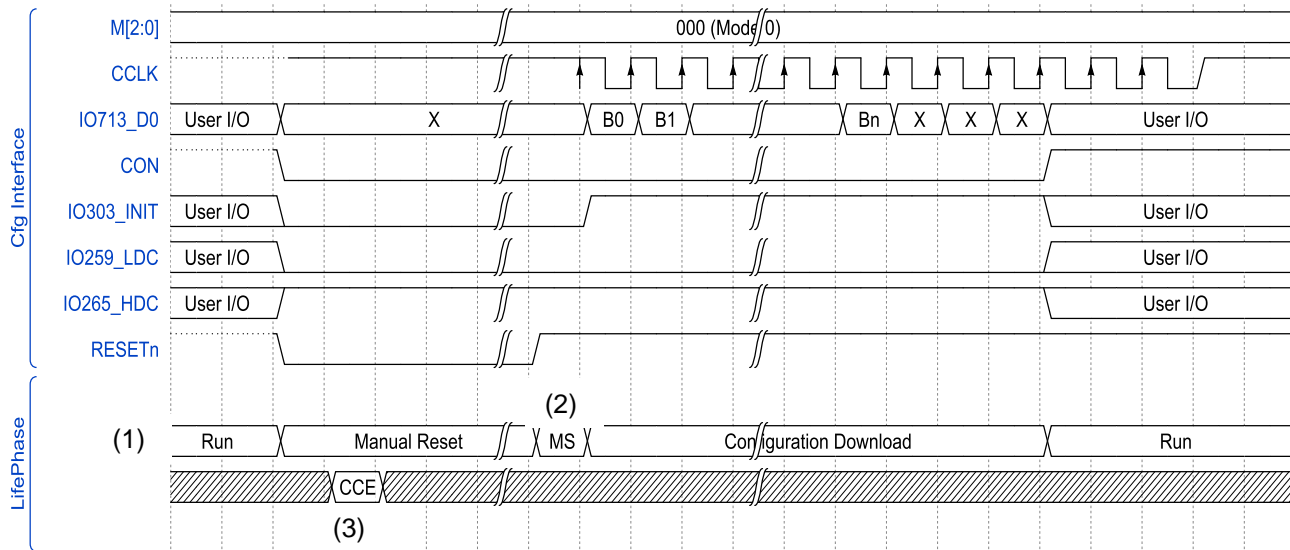

**[Run]:** Once configured, the ATF697FF reconfigurable unit enters in Run lifephase. In this lifephase, the loaded application runs and its own lifephases are taken into account. This lifephase is entered few CCLK cycles after the ATF697FF reconfigurable unit has sensed the postamble, it then releases the configuration interface signals and all multiplexed signals are set to their GPIO function:

- M0, M1, M2. these signals remain inputs and are not used anymore,
- CCLK: this signal is an input with pull-up and is not used anymore,
- IO713\_D0: this signal becomes a User I/O and takes its application configuration,
- CON: this signal is released to a high logic level,
- IO303\_INIT: this signal becomes a User I/O and takes its application configuration,
- IO259\_LDC: this signal becomes a User I/O and takes its application configuration,
- IO265\_HDC: this signal becomes a User I/O and takes its application configuration,
- FPGA\_RESET\* : this signal is an input which immediately reset the configuration logic to a Manual Reset lifephase.

### 11.2.2.2 Configuration Download from Manual Reset in mode 0

The chronogram described here after presents the sequence of ATF697FF reconfigurable unit from a **Manual Reset** until **Run**. This is the global overview of ATF697FF reconfigurable unit automatic configuration download after a Manual Reset.

**Figure 11-4. ATF697FF reconfigurable unit: Configuration Download from Manual Reset**

- Notes:
1. This line shows the different lifephase viewable in life cycle diagram described in **OperatingModes / Lifephases** section,
  2. “MS” means **Mode Sampling** lifephase,
  3. “CCE” means Clear Cycle End.

**[Manual Reset]:** During the Manual Reset lifephase, the ATF697FF reconfigurable unit starts to drive the signal regarding the configuration download interfaces as defined below. This phase is entered when the FPGA\_RESET\* pin is activated. The end of this lifephase is marked by the rising edge of IO303\_INIT pin. During Manual Reset lifephase, the Clear Cycle operation (ended by CCE in the figure above) starts immediately and is performed in approximately 2 ms. If the FPGA\_RESET\* pin is activated during less than the 2 ms required for the Clear Cycle operation, the ATF697FF reconfigurable unit remains in Manual Reset until CCE time:

- M0, M1, M2. these signals are inputs and not used,
- CCLK: this signal is internally pulled-up,
- IO713\_D0: this signal is internally pulled-up,
- CON: this signal is driven to a low logic level,
- IO303\_INIT: this signal is driven low until the FPGA\_RESET\* pin is released,
- IO259\_LDC: the Low During Configuration is driven to a low logic level,
- IO265\_HDC: the High During Configuration is driven to a high logic level,
- FPGA\_RESET\* : this signal is an input which is active during Manual Reset lifephase.

**[Mode Sampling]:** During the Mode Sampling lifephase, the ATF697FF reconfigurable unit continues to drive the signal regarding configuration download interfaces. In addition, Mode Pins (M0, M1, M2) are sensed:

- M0, M1, M2. these signals are inputs and sensed to determine the used mode. If mode 0 is sampled (as shown in the figure above), the automatic configuration download starts.

- CCLK: this signal is internally pulled-up,
- IO713\_D0: this signal takes the value output by the EEPROM (first bit of the EEPROM),
- CON: this signal is driven to a low logic level,
- IO303\_INIT: this signal is internally pulled-up,
- IO259\_LDC: the Low During Configuration is driven to a low logic level,
- IO265\_HDC: the High During Configuration is driven to a high logic level,
- FPGA\_RESET\* : this signal is an input which immediately reset the configuration logic to a Manual Reset lifephase.

**[Configuration Download]:** During the Configuration Download lifephase, the ATF697FF reconfigurable unit continues to drive the signal regarding configuration download interfaces, this lifephase starts when CCLK pin is output:

- M0, M1, M2. these signals remain inputs and are not used anymore,
- CCLK: this signal is output as clock source for the serial EEPROM memory. At each rising edge of CCLK, the EEPROM memory outputs a new bit while the ATF697FF reconfigurable unit senses the previous bit. By default, the CCLK frequency toggles at a frequency of approximately 900 KHz.
- IO713\_D0: this signal is sampled by the FPGA at each rising edge of CCLK. It is the DATA output of the EEPROM memory,
- CON: this signal is driven to a low logic level,
- IO303\_INIT: this signal is internally pulled-up and is used as an error monitoring pin Refer to **Data Link Protection** section for serial configuration,
- IO259\_LDC: the Low During Configuration is driven to a low logic level,
- IO265\_HDC: the High During Configuration is driven to a high logic level,
- FPGA\_RESET\* : this signal is an input which immediately reset the configuration logic to a Manual Reset lifephase.

**[Run]:** Once configured, the ATF697FF reconfigurable unit enters in Run lifephase. In this lifephase, the loaded application runs and its own lifephases are taken into account. This lifephase is entered few CCLK cycles after the ATF697FF reconfigurable unit has sensed the postamble, it then releases the configuration interface signals and all multiplexed signals are set to their GPIO function:

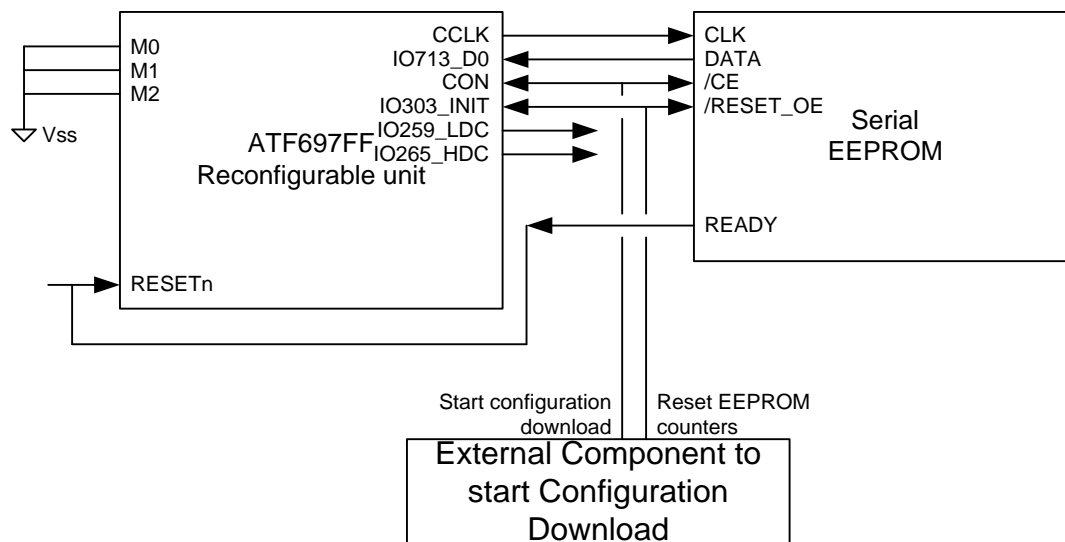

- M0, M1, M2. these signals remain inputs and are not used anymore,
- CCLK: this signal is an input with pull-up and is not used anymore,
- IO713\_D0: this signal becomes a User I/O and takes its application configuration,
- CON: this signal is released to a high logic level,
- IO303\_INIT: this signal becomes a User I/O and takes its application configuration,
- IO259\_LDC: this signal becomes a User I/O and takes its application configuration,
- IO265\_HDC: this signal becomes a User I/O and takes its application configuration,
- FPGA\_RESET\* : this signal is an input which immediately reset the configuration logic to a Manual Reset lifephase.

### 11.2.2.3 Restart of Configuration Download in mode 0

In mode 0, it is possible to restart the configuration download phase without proceeding to a FPGA reboot (Power-On reset or Manual Reset). For this, it is required to use an external component in order to trig the start of the configuration download. The following synoptic shows the required signal to be used for restart of configuration download purpose in mode 0.

Figure 11-5. ATF697FF reconfigurable unit restart configuration download in mode 0

The chronogram described here after presents the sequence of ATF697FF reconfigurable unit from a **Run** until **Run**. This is the global overview of ATF697FF reconfigurable unit restart of configuration download when in **Run**.

Figure 11-6. ATF697FF reconfigurable unit : Restart of Configuration Download in mode 0

**[Run]:** In **Run** lifephase, the multiplexed pin of the ATF697FF reconfigurable unit are in their GPIO function and as configured by the already loaded application. This lifephase is exiting to enter in **Configuration Download** as soon as the CON pin is driven to a low logic level by an external master:

- M0, M1, M2. these signals remain inputs and are not used anymore (Mode is already sampled),
- CCLK: this signal is an input with pull-up and is not used,
- IO713\_D0: this signal remains a User I/O,
- CON: this signal is released to a high logic level by the ATF697FF reconfigurable unit itself,

- IO303\_INIT: this signal remains a User I/O,
- IO259\_LDC: this signal remains a User I/O,
- IO265\_HDC: this signal remains a User I/O,
- FPGA\_RESET\* : this signal is an input which immediately reset the configuration logic to a Manual Reset lifephase.

**[Configuration Download]:** During the Configuration Download lifephase, the ATF697FF reconfigurable unit starts to drive the signal regarding configuration download interfaces, this lifephase starts when CON is lowered by an external master component:

- M0, M1, M2. these signals remain inputs and are not used anymore,
- CCLK: this signal is output as clock source for the serial EEPROM memory. At each rising edge of CCLK, the EEPROM memory outputs a new bit while the ATF697FF reconfigurable unit senses the previous bit. By default, the CCLK frequency toggles at a frequency of approximately 900 KHz.
- IO713\_D0: this signal is sampled by the FPGA at each rising edge of CCLK. It is the DATA output of the EEPROM memory,
- CON: this signal shall be first maintained to a low logic level by an external master component. The configuration download starts immediately and CCLK is directly output. Once the ATF697FF reconfigurable unit has sampled the CON pin to low during three CCLK periods, it starts to drive the CON pin to a low logic level. Then the external master component shall release the CON signal,
- IO303\_INIT: this signal is internally pulled-up and is used as an error monitoring pin. Refer to **Data Link Protection** section for serial configuration,
- IO259\_LDC: the Low During Configuration is driven to a low logic level,
- IO265\_HDC: the High During Configuration is driven to a high logic level,
- FPGA\_RESET\* : this signal is an input which immediately reset the configuration logic to a Manual Reset lifephase.

**[Run]:** Once configured, the ATF697FF reconfigurable unit enters in Run lifephase. In this lifephase, the loaded application runs and its own lifephases are taken into account. This lifephase is entered few CCLK cycles after the ATF697FF reconfigurable unit has sensed the postamble, it then releases the configuration interface signals and all multiplexed signals are set to their GPIO function:

- M0, M1, M2. these signals remain inputs and are not used anymore,
- CCLK: this signal is an input with pull-up and is not used anymore,
- IO713\_D0: this signal becomes a User I/O and takes its application configuration,
- CON: this signal is released to a high logic level,
- IO303\_INIT: this signal becomes a User I/O and takes its application configuration,
- IO259\_LDC: this signal becomes a User I/O and takes its application configuration,
- IO265\_HDC: this signal becomes a User I/O and takes its application configuration,
- FPGA\_RESET\* : this signal is an input which immediately reset the configuration logic to a Manual Reset lifephase.

### 11.2.3 Slave Modes

In slave modes, configuration is always initiated by an external signal. Data is applied to the device on the rising edge of CCLK. In Slave Serial Mode, the device receives serial configuration data. CCLK is not generated in slave modes.

### 11.2.3.1 Mode 1

The mode 1 is one of the Slave Serial Mode configuration download. In this mode, the ATF697FF reconfigurable unit is coupled to a serial EEPROM and shall be externally driven for configuration download purpose. The following synoptic shows the required interface to be used for configuration download purpose in mode 1.

**Figure 11-7. ATF697FF reconfigurable unit FPGA environment : configuration download in mode 1**

### Power-On Reset in mode 1

The chronogram described here after presents the sequence of ATF697FF reconfigurable unit from a **Power-On Reset** until **Idle**. This is the global overview of ATF697FF reconfigurable unit Power-On Reset sequence. At the end of this sequence, the ATF697FF reconfigurable unit remains unconfigured and is ready for configuration download in slave mode.

Figure 11-8. ATF697FF reconfigurable unit Power-On Reset in mode 1

- Notes:
1. This line shows the different lifephase viewable in life cycle diagram described in **OperatingModes / Lifephases** section,
  2. “CCE” means Clear Cycle End.

**[Power-On-Reset]:** During the Power-On Reset lifephase, the ATF697FF reconfigurable unit starts to drive the signal regarding the configuration download interfaces as defined below. The end of this lifephase is marked by the rising edge of IO303\_INIT pin:

- M0, M1, M2. these signals are inputs and not used,
- CCLK: this signal is internally pulled-up,
- IO713\_D0: this signal is internally pulled-up,
- CON: this signal is driven to a low logic level,
- IO303\_INIT: this signal is internally pulled-up until the end of the Clear Cycle operation (CCE). At this time, IO303\_INIT is driven to a low logic level during approximately 1 us,
- IO259\_LDC: the Low During Configuration is driven to a low logic level,
- IO265\_HDC: the High During Configuration is driven to a high logic level,
- IO547\_CS0: this signal is internally pulled-up,
- FPGA\_RESET\* : this signal is an input which has no effect during the Power-On Reset lifephase.

**[Mode Sampling]:** During the Mode Sampling lifephase, the ATF697FF reconfigurable unit continues to drive the signal regarding configuration download interfaces. In addition, Mode Pins (M0, M1, M2) are sensed:

- M0, M1, M2. these signals are inputs and sensed to determine the used mode. If mode 0 is sampled (as shown in the figure above), the automatic configuration download starts.
- CCLK: this signal is internally pulled-up,
- IO713\_D0: this signal takes the value output by the EEPROM (first bit of the EEPROM),
- CON: this signal is driven to a low logic level,
- IO303\_INIT: this signal is internally pulled-up,
- IO259\_LDC: the Low During Configuration is driven to a low logic level,
- IO265\_HDC: the High During Configuration is driven to a high logic level,
- IO547\_CS0: this signal is internally pulled-up,
- FPGA\_RESET\* : this signal is an input which immediately reset the configuration logic to a Manual Reset lifephase.

**[Idle]:** During the Idle lifephase, the ATF697FF reconfigurable unit continues releases the configuration download interface, this lifephase starts when CON and IO303\_INIT pins are released:

- M0, M1, M2. these signals remain inputs and are not used anymore,
- CCLK: this signal is internally pulled-up,
- IO713\_D0: this signal takes its GPIO function and is internally pulled-up,
- CON: this signal is released to a high logic level,
- IO303\_INIT: this signal takes its GPIO function and is internally pulled-up. Refer to **Data Link Protection** section for serial configuration,
- IO259\_LDC: this signal takes its GPIO function and is internally pulled-up,
- IO265\_HDC: this signal takes its GPIO function and is internally pulled-up,
- IO547\_CS0: this signal takes its GPIO function and is internally pulled-up,
- FPGA\_RESET\* : this signal is an input which immediately reset the configuration logic to a Manual Reset lifephase.

## Manual Reset in mode 1

The chronogram described here after presents the sequence of ATF697FF reconfigurable unit from a **Manual Reset** until **Idle**. This is the global overview of ATF697FF reconfigurable unit Manual Reset sequence. At the end of this sequence, the ATF697FF reconfigurable unit remains unconfigured and is ready for configuration download in slave mode.

Figure 11-9. ATF697FF reconfigurable unit : Manual Reset in mode 1

- Notes:
1. This line shows the different lifephase viewable in life cycle diagram described in **OperatingModes / Lifephases** section,
  2. “MS” means **Mode Sampling** lifephase,
  3. “CCE” means Clear Cycle End.

**[Manual Reset]:** During the Manual Reset lifephase, the ATF697FF reconfigurable unit starts to drive the signal regarding the configuration download interfaces as defined below. This phase is entered when the FPGA\_RESET\* pin is activated. The end of this lifephase is marked by the rising edge of IO303\_INIT pin. During Manual Reset lifephase, the Clear Cycle operation (ended by CCE in the figure above) starts immediately and is performed in approximately 2 ms. If the FPGA\_RESET\* pin is activated during less than the 2 ms required for the Clear Cycle operation, the ATF697FF reconfigurable unit remains in Manual Reset until CCE time:

- M0, M1, M2. these signals are inputs and not used,
- CCLK: this signal is internally pulled-up,
- IO713\_D0: this signal is internally pulled-up,

- CON: this signal is driven to a low logic level,
- IO303\_INIT: this signal is driven low until the FPGA\_RESET\* pin is released,
- IO259\_LDC: the Low During Configuration is driven to a low logic level,
- IO265\_HDC: the High During Configuration is driven to a high logic level,
- IO547\_CS0: this signal is internally pulled-up,
- FPGA\_RESET\* : this signal is an input which is active during Manual Reset lifephase.

**[Mode Sampling]:** During the Mode Sampling lifephase, the ATF697FF reconfigurable unit continues to drive the signal regarding configuration download interfaces. In addition, Mode Pins (M0, M1, M2) are sensed:

- M0, M1, M2. these signals are inputs and sensed to determine the used mode. If mode 0 is sampled (as shown in the figure above), the automatic configuration download starts.
- CCLK: this signal is internally pulled-up,
- IO713\_D0: this signal takes the value output by the EEPROM (first bit of the EEPROM),
- CON: this signal is driven to a low logic level,
- IO303\_INIT: this signal is internally pulled-up,
- IO259\_LDC: the Low During Configuration is driven to a low logic level,
- IO265\_HDC: the High During Configuration is driven to a high logic level,
- IO547\_CS0: this signal is internally pulled-up,
- FPGA\_RESET\* : this signal is an input which immediately reset the configuration logic to a Manual Reset lifephase.

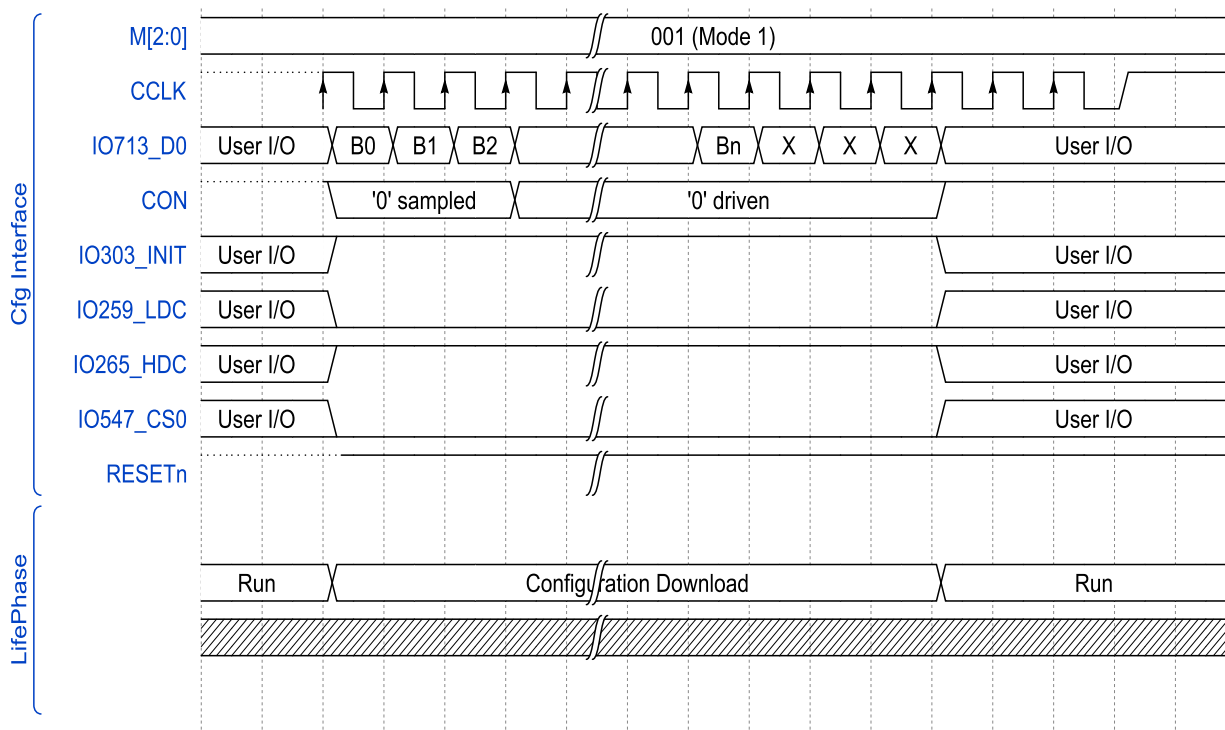

**[Idle]:** During the Idle lifephase, the ATF697FF reconfigurable unit continues releases the configuration download interface, this lifephase starts when CON and IO303\_INIT pins are released:

- M0, M1, M2. these signals remain inputs and are not used anymore,
- CCLK: this signal is internally pulled-up,
- IO713\_D0: this signal takes its GPIO function and is internally pulled-up,
- CON: this signal is released to a high logic level,
- IO303\_INIT: this signal takes its GPIO function and is internally pulled-up. Refer to **Data Link Protection** section for serial configuration,
- IO259\_LDC: this signal takes its GPIO function and is internally pulled-up,
- IO265\_HDC: this signal takes its GPIO function and is internally pulled-up,
- IO547\_CS0: this signal takes its GPIO function and is internally pulled-up,
- FPGA\_RESET\* : this signal is an input which immediately reset the configuration logic to a Manual Reset lifephase.

## Configuration Download in mode 1

The chronogram described here after presents the sequence of ATF697FF reconfigurable unit from **Run** or **Idle** until **Run**. This is the global overview of ATF697FF reconfigurable unit Configuration Download sequence in mode 1. At the end of this sequence, the ATF697FF reconfigurable unit is configured and the loaded application runs.

Figure 11-10. ATF697FF reconfigurable unit: Configuration Download in mode 1

**[Run]:** In **Run** lifephase, the multiplexed pin of the ATF697FF reconfigurable unit are in their GPIO function and as configured by the already loaded application. This lifephase is exiting to enter in **Configuration Download** as soon as the CON pin is driven to a low logic level by an external master:

- M0, M1, M2. these signals remain inputs and are not used anymore (Mode is already sampled),
- CCLK: this signal is an input with pull-up and is not used,
- IO713\_D0: this signal remains a User I/O,
- CON: this signal is released to a high logic level by the ATF697FF reconfigurable unit itself,
- IO303\_INIT: this signal remains a User I/O,
- IO259\_LDC: this signal remains a User I/O,
- IO265\_HDC: this signal remains a User I/O,
- IO547\_CS0: this signal remains a User I/O,
- FPGA\_RESET\* : this signal is an input which immediately reset the configuration logic to a Manual Reset lifephase.

**[Configuration Download]:** During the Configuration Download lifephase, the ATF697FF reconfigurable unit starts to drive the signal regarding configuration download interfaces, this lifephase starts when CON is lowered by an external master component:

- M0, M1, M2. these signals remain inputs and are not used anymore,

- CCLK: this signal is an input and shall be provided by the external master component as clock source for the serial EEPROM memory and the ATF697FF reconfigurable unit. At each rising edge of CCLK, the EEPROM memory outputs a new bit while the ATF697FF reconfigurable unit senses the previous bit.
- IO713\_D0: this signal is sampled by the FPGA at each rising edge of CCLK. It is the DATA output of the EEPROM memory,
- CON: this signal shall be first maintained to a low logic level by an external master component. The configuration download starts immediately and CCLK is directly output. Once the ATF697FF reconfigurable unit has sampled the CON pin to low during three CCLK periods, it starts to drive the CON pin to a low logic level. Then the external master component shall release the CON signal,
- IO303\_INIT: this signal is internally pulled-up and is used as an error monitoring pin. Refer to **Data Link Protection** section for serial configuration,
- IO259\_LDC: the Low During Configuration is driven to a low logic level,
- IO265\_HDC: the High During Configuration is driven to a high logic level,
- IO547\_CS0: this signal shall be driven low during the whole configuration download lifephase,
- FPGA\_RESET\* : this signal is an input which immediately reset the configuration logic to a Manual Reset lifephase.

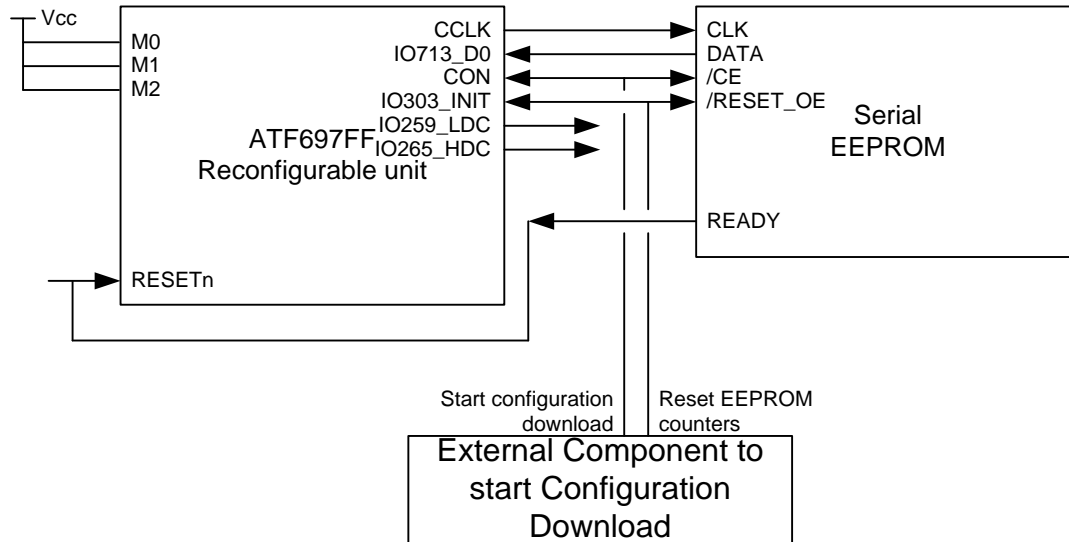

**[Run]:** Once configured, the ATF697FF reconfigurable unit enters in Run lifephase. In this lifephase, the loaded application runs and its own lifephases are taken into account. This lifephase is entered few CCLK cycles after the ATF697FF reconfigurable unit has sensed the postamble, it then releases the configuration interface signals and all multiplexed signals are set to their GPIO function:

- M0, M1, M2. these signals remain inputs and are not used anymore,
- CCLK: this signal is an input with pull-up and is not used anymore,
- IO713\_D0: this signal becomes a User I/O and takes its application configuration,
- CON: this signal is released to a high logic level,
- IO303\_INIT: this signal becomes a User I/O and takes its application configuration,
- IO259\_LDC: this signal becomes a User I/O and takes its application configuration,
- IO265\_HDC: this signal becomes a User I/O and takes its application configuration,
- IO547\_CS0: this signal becomes a User I/O and takes its application configuration,
- FPGA\_RESET\* : this signal is an input which immediately reset the configuration logic to a Manual Reset lifephase.

### 11.2.3.2 Mode 7

The mode 7 is one of the Slave Serial Mode configuration download. In this mode, the ATF697FF reconfigurable unit is coupled to a serial EEPROM and shall be externally driven for configuration download purpose. The following synoptic shows the required signal to be used for configuration download purpose in mode 7.

Figure 11-11. ATF697FF reconfigurable unit A environment : configuration download in mode 7

### Power-On Reset in mode 7

The chronogram described here after presents the sequence of ATF697FF reconfigurable unit from a **Power-On Reset** until **Idle**. This is the global overview of ATF697FF reconfigurable unit Power-On Reset sequence. At the end of this sequence, the ATF697FF reconfigurable unit remains unconfigured and is ready for configuration download in slave mode.

Figure 11-12. ATF697FF reconfigurable unit Power-On Reset in mode 7

- Notes:
1. This line shows the different lifephase viewable in life cycle diagram described in **OperatingModes / Lifephases** section,
  2. “CCE” means Clear Cycle End.

**[Power-On-Reset]:** During the Power-On Reset lifephase, the ATF697FF reconfigurable unit starts to drive the signal regarding the configuration download interfaces as defined below. The end of this lifephase is marked by the rising edge of IO303\_INIT pin:

- M0, M1, M2. these signals are inputs and not used,
- CCLK: this signal is internally pulled-up,
- IO713\_D0: this signal is internally pulled-up,
- CON: this signal is driven to a low logic level,
- IO303\_INIT: this signal is internally pulled-up until the end of the Clear Cycle operation (CCE). At this time, IO303\_INIT is driven to a low logic level during approximately 1 us,
- IO259\_LDC: the Low During Configuration is driven to a low logic level,
- IO265\_HDC: the High During Configuration is driven to a high logic level,
- FPGA\_RESET\* : this signal is an input which has no effect during the Power-On Reset lifephase.

**[Mode Sampling]:** During the Mode Sampling lifephase, the ATF697FF reconfigurable unit continues to drive the signal regarding configuration download interfaces. In addition, Mode Pins (M0, M1, M2) are sensed:

- M0, M1, M2. these signals are inputs and sensed to determine the used mode. If mode 0 is sampled (as shown in the figure above), the automatic configuration download starts.

- CCLK: this signal is internally pulled-up,
- IO713\_D0: this signal takes the value output by the EEPROM (first bit of the EEPROM),
- CON: this signal is driven to a low logic level,
- IO303\_INIT: this signal is internally pulled-up,
- IO259\_LDC: the Low During Configuration is driven to a low logic level,
- IO265\_HDC: the High During Configuration is driven to a high logic level,
- FPGA\_RESET\* : this signal is an input which immediately reset the configuration logic to a Manual Reset lifephase.

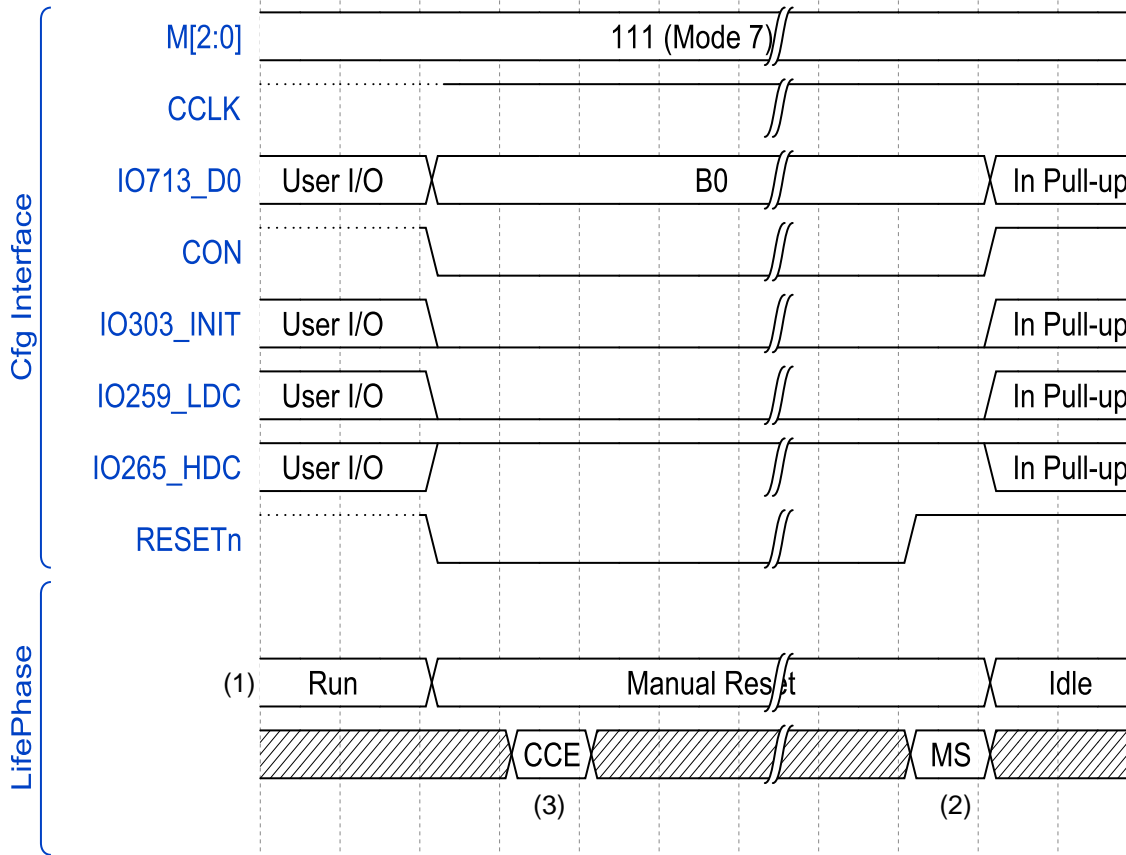

**[Idle]:** During the Idle lifephase, the ATF697FF reconfigurable unit continues releases the configuration download interface, this lifephase starts when CON and IO303\_INIT pins are released:

- M0, M1, M2. these signals remain inputs and are not used anymore,
- CCLK: this signal is internally pulled-up,
- IO713\_D0: this signal takes its GPIO function and is internally pulled-up,
- CON: this signal is released to a high logic level,
- IO303\_INIT: this signal takes its GPIO function and is internally pulled-up. Refer to **Data Link Protection** section for serial configuration,
- IO259\_LDC: this signal takes its GPIO function and is internally pulled-up,
- IO265\_HDC: this signal takes its GPIO function and is internally pulled-up,
- IO547\_CS0: this signal takes its GPIO function and is internally pulled-up,
- FPGA\_RESET\* : this signal is an input which immediately reset the configuration logic to a Manual Reset lifephase.

## Manual Reset in mode 7

The chronogram described here after presents the sequence of ATF697FF reconfigurable unit from a **Manual Reset** until **Idle**. This is the global overview of ATF697FF reconfigurable unit Manual Reset sequence. At the end of this sequence, the ATF697FF reconfigurable unit remains unconfigured and is ready for configuration download in slave mode.

Figure 11-13. ATF697FF reconfigurable unit: Manual Reset in mode 7

Notes: 1. This line shows the different lifephase viewable in life cycle diagram described in **OperatingModes / Lifephases** section,

2. "MS" means **Mode Sampling** lifephase,

3. "CCE" means Clear Cycle End.

**[Manual Reset]:** During the Manual Reset lifephase, the ATF697FF reconfigurable unit starts to drive the signal regarding the configuration download interfaces as defined below. This phase is entered when the FPGA\_RESET\* pin is activated. The end of this lifephase is marked by the rising edge of IO303\_INIT pin. During Manual Reset lifephase, the Clear Cycle operation (ended by CCE in the figure above) starts immediately and is performed in approximately 2 ms. If the FPGA\_RESET\* pin is activated during less than the 2 ms required for the Clear Cycle operation, the ATF697FF reconfigurable unit remains in Manual Reset until CCE time:

- M0, M1, M2. these signals are inputs and not used,
- CCLK: this signal is internally pulled-up,
- IO713\_D0: this signal is internally pulled-up,

- CON: this signal is driven to a low logic level,
- IO303\_INIT: this signal is driven low until the FPGA\_RESET\* pin is released,
- IO259\_LDC: the Low During Configuration is driven to a low logic level,
- IO265\_HDC: the High During Configuration is driven to a high logic level,
- FPGA\_RESET\* : this signal is an input which is active during Manual Reset lifephase.

**[Mode Sampling]:** During the Mode Sampling lifephase, the ATF697FF reconfigurable unit continues to drive the signal regarding configuration download interfaces. In addition, Mode Pins (M0, M1, M2) are sensed:

- M0, M1, M2. these signals are inputs and sensed to determine the used mode. If mode 0 is sampled (as shown in the figure above), the automatic configuration download starts.
- CCLK: this signal is internally pulled-up,
- IO713\_D0: this signal takes the value output by the EEPROM (first bit of the EEPROM),
- CON: this signal is driven to a low logic level,
- IO303\_INIT: this signal is internally pulled-up,
- IO259\_LDC: the Low During Configuration is driven to a low logic level,
- IO265\_HDC: the High During Configuration is driven to a high logic level,
- FPGA\_RESET\*: this signal is an input which immediately reset the configuration logic to a Manual Reset lifephase.

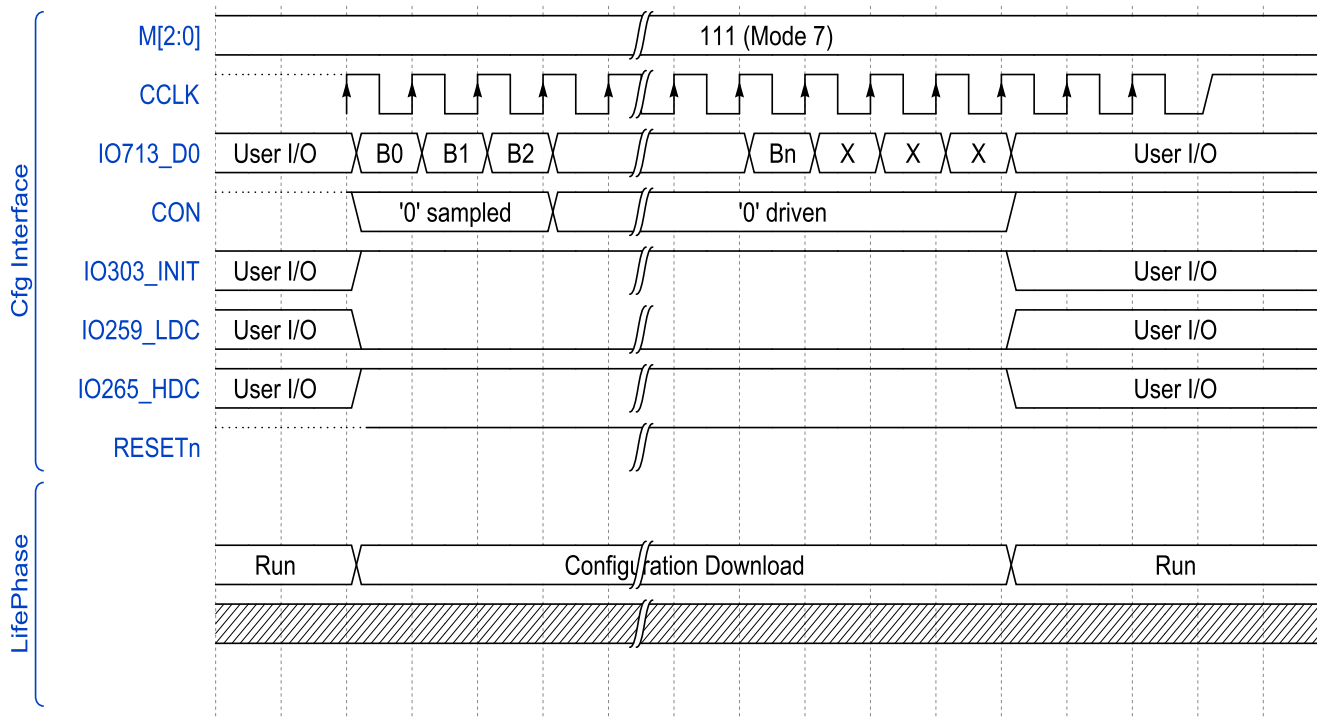

**[Idle]:** During the Idle lifephase, the ATF697FF reconfigurable unit continues releases the configuration download interface, this lifephase starts when CON and IO303\_INIT pins are released:

- M0, M1, M2. these signals remain inputs and are not used anymore,
- CCLK: this signal is internally pulled-up,
- IO713\_D0: this signal takes its GPIO function and is internally pulled-up,
- CON: this signal is released to a high logic level,
- IO303\_INIT: this signal takes its GPIO function and is internally pulled-up. Refer to **Data Link Protection** section for serial configuration,
- IO259\_LDC: this signal takes its GPIO function and is internally pulled-up,
- IO265\_HDC: this signal takes its GPIO function and is internally pulled-up,
- FPGA\_RESET\* : this signal is an input which immediately reset the configuration logic to a Manual Reset lifephase.

## Configuration Download in mode 7

The chronogram described here after presents the sequence of ATF697FF reconfigurable unit from **Run** or **Idle** until **Run**. This is the global overview of ATF697FF reconfigurable unit Configuration Download sequence in mode 1. At the end of this sequence, the ATF697FF reconfigurable unit is configured and the loaded application runs.

Figure 11-14. ATF697FF reconfigurable unit: Configuration Download in mode 7

**[Run]:** In **Run** lifephase, the multiplexed pin of the ATF697FF reconfigurable unit are in their GPIO function and as configured by the already loaded application. This lifephase is exiting to enter in **Configuration Download** as soon as the CON pin is driven to a low logic level by an external master:

- M0, M1, M2. these signals remain inputs and are not used anymore (Mode is already sampled),
- CCLK: this signal is an input with pull-up and is not used,
- IO713\_D0: this signal remains a User I/O,
- CON: this signal is released to a high logic level by the ATF697FF reconfigurable unit itself,
- IO303\_INIT: this signal remains a User I/O,
- IO259\_LDC: this signal remains a User I/O,
- IO265\_HDC: this signal remains a User I/O,
- FPGA\_RESET\* : this signal is an input which immediately reset the configuration logic to a Manual Reset lifephase.

**[Configuration Download]:** During the Configuration Download lifephase, the ATF697FF reconfigurable unit starts to drive the signal regarding configuration download interfaces, this lifephase starts when CON is lowered by an external master component:

- M0, M1, M2. these signals remain inputs and are not used anymore,
- CCLK: this signal is an input and shall be provided by the external master component as clock source for the serial EEPROM memory and the ATF697FF reconfigurable unit. At each rising edge of CCLK, the EEPROM memory outputs a new bit while the ATF697FF reconfigurable unit senses the previous bit.

- IO713\_D0: this signal is sampled by the FPGA at each rising edge of CCLK. It is the DATA output of the EEPROM memory,
- CON: this signal shall be first maintained to a low logic level by an external master component. The configuration download starts immediately and CCLK is directly output. Once the ATF697FF reconfigurable unit has sampled the CON pin to low during three CCLK periods, it starts to drive the CON pin to a low logic level. Then the external master component shall release the CON signal,
- IO303\_INIT: this signal is internally pulled-up and is used as an error monitoring pin. Refer to **Data Link Protection** section for serial configuration,
- IO259\_LDC: the Low During Configuration is driven to a low logic level,
- IO265\_HDC: the High During Configuration is driven to a high logic level,
- FPGA\_RESET\* : this signal is an input which immediately reset the configuration logic to a Manual Reset lifephase.

**[Run]:** Once configured, the ATF697FF reconfigurable unit enters in Run lifephase. In this lifephase, the loaded application runs and its own lifephases are taken into account. This lifephase is entered few CCLK cycles after the ATF697FF reconfigurable unit has sensed the postamble, it then releases the configuration interface signals and all multiplexed signals are set to their GPIO function:

- M0, M1, M2. these signals remain inputs and are not used anymore,
- CCLK: this signal is an input with pull-up and is not used anymore,
- IO713\_D0: this signal becomes a User I/O and takes its application configuration,
- CON: this signal is released to a high logic level,
- IO303\_INIT: this signal becomes a User I/O and takes its application configuration,
- IO259\_LDC: this signal becomes a User I/O and takes its application configuration,
- IO265\_HDC: this signal becomes a User I/O and takes its application configuration,
- FPGA\_RESET\* : this signal is an input which immediately reset the configuration logic to a Manual Reset lifephase.

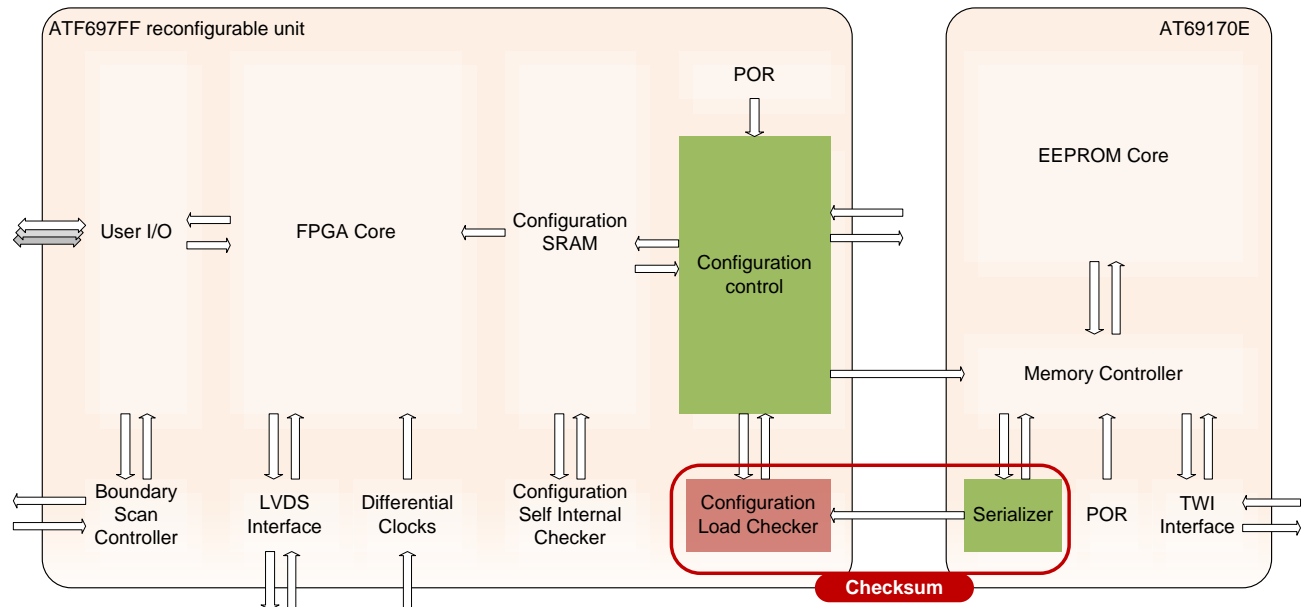

### 11.2.3.3 Data Link Protection

The ATF697FF reconfigurable unit is capable to secure the mechanism involved during the configuration download in order to prevent wrong configuration of the FPGA.

The following schematic represents an overview of the system made by the FPGA and a serial EEPROM memory. The highlighted modules show where the protection of the configuration download link takes place.

Figure 11-15. ATF697FF reconfigurable unit Configuration Download Link

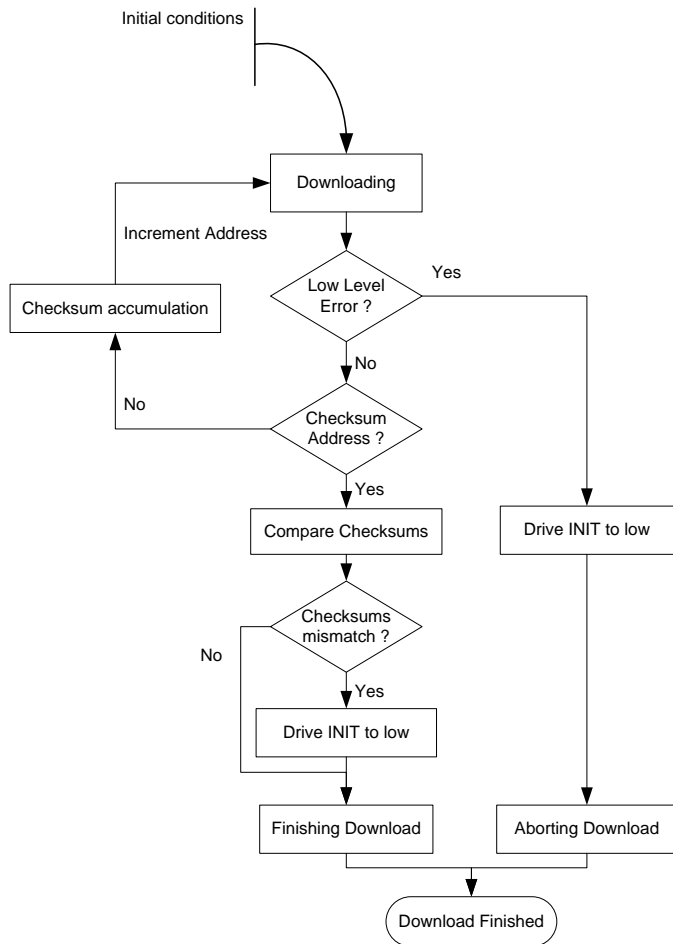

Two kinds of errors are managed during the configuration:

- Low Level Errors
- Such protection is used to warranty that the communication protocol on the FPGA serial communication link is correctly handled all along the configuration process. In addition, the low level error management ensures that no erroneous access to the FPGA configuration SRAM will be attempted.
- When detected, the low level results in “Aborting Download”. This means that all the steps from a configuration download are not performed. The consequence is that the bitstream is partially loaded and can result in an unoperating FPGA,
- Checksum Errors
- This protection is used at the end of the configuration download to verify that there were no corruptions of the data stream during the transfer.
- When detected, the checksum error results in “Finishing download”. This means that all the steps from a nominal configuration download are executed until entering in **Run** lifephase.

The error detection mechanism follows the flow chart presented here after.

**Figure 11-16. Management of configuration download link protection**

## Low level Errors management

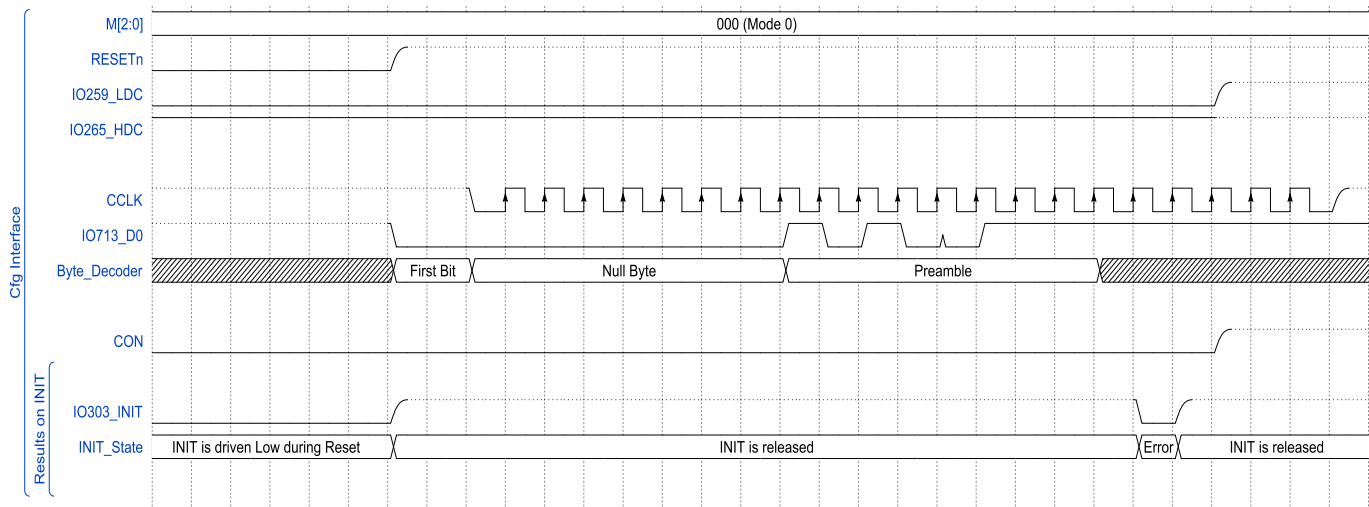

These errors have the highest priority and terminate by a configuration download abort. They are managed in the same way whatever is the used serial mode (Mode 0, 1 or 7).

The low level errors are detected in case of bad values regarding the following elements:

- “Preamble” mismatch → different from “10110111”
- “Start Address” mismatch → if the start address of a window is corrupted,
- “Stop Address” mismatch → if the stop address of a window is corrupted,
- “Postamble” mismatch → different from “11100111”.

In case of low level error, INIT is driven low during one CCLK clock period few clock cycles after the byte in default. Then, INIT is released and CON is released. The configuration download is so finished.

**Figure 11-17. ATF697FF reconfigurable unit Preamble mismatch behavior in mode 0**

## Checksum Errors management

During the generation of an application bitstream, a checksum is computed with a specific algorithm by IDS tool and stored in the bitstream checksum zone. This checksum is the reference for checksum error management.

All along the configuration download, the “configuration load checker” calculates on-the-fly a checksum byte by accumulating all effective data of the downloaded bitstream with a hardcoded algorithm.

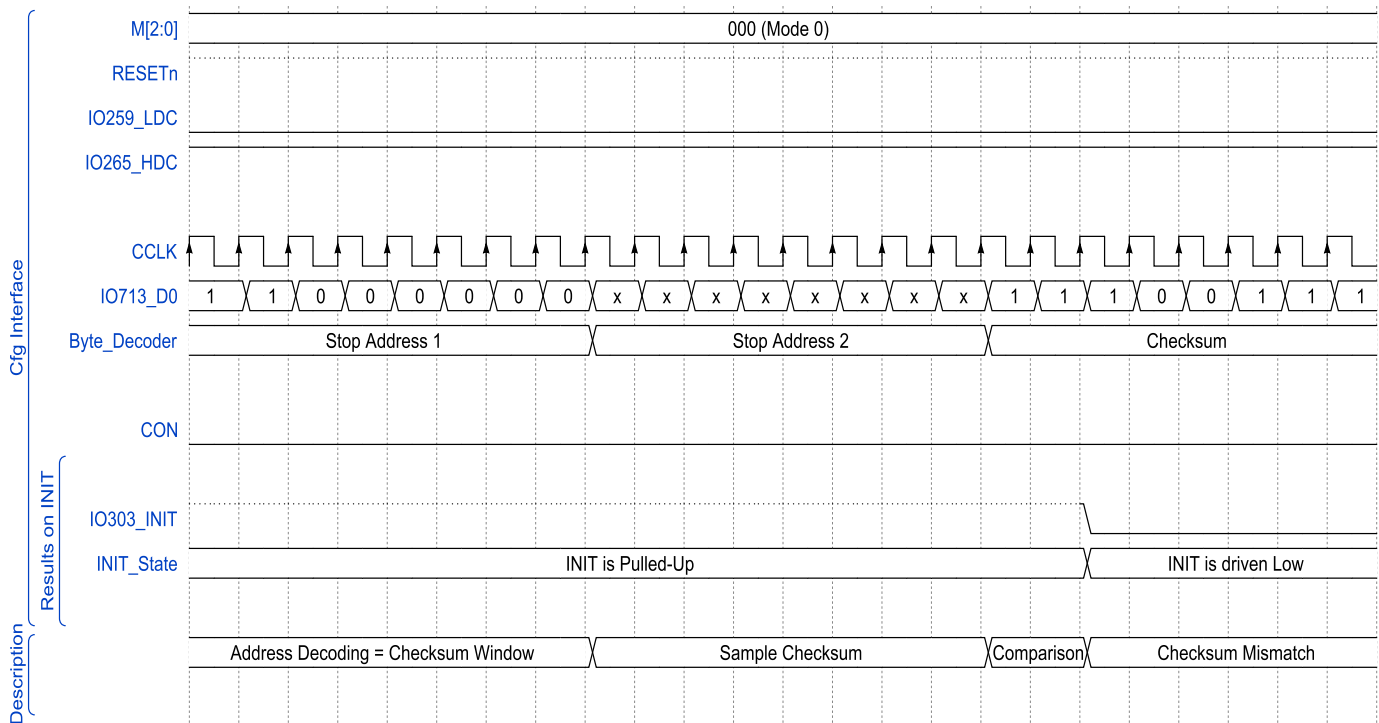

Once the FPGA configuration reaches the checksum zone, it compares the reference downloaded checksum together with the checksum accumulated during the configuration download. In case of mismatched values, INIT is driven low to notify that errors occur during the download procedure.

All data loaded in the FPGA configuration SRAM will be taken into account by the FPGA parts.

On ATF697FF reconfigurable unit, the checksum window is addressed as follow and is one byte sized:

- Start Address: Byte0 = 0x00000000, Byte 1 = 0x00000000, Byte 2 = 0x11000000,
- Stop Address: Byte0 = 0x00000000, Byte 1 = 0x00000000, Byte 2 = 0x11000000

Figure 11-18. ATF697FF reconfigurable unit Checksum error behavior in mode 0

## 11.3 Configuration Integrity Management

While the download of the bit-stream from the EEPROM (or configuration master) to the FPGA is checked through communication link protection, the ATF697FF reconfigurable unit also provides the features for verification of the configuration once the FPGA configuration is finished. Two services are provided to manage the integrity of the configuration.

### 11.3.1 Check function

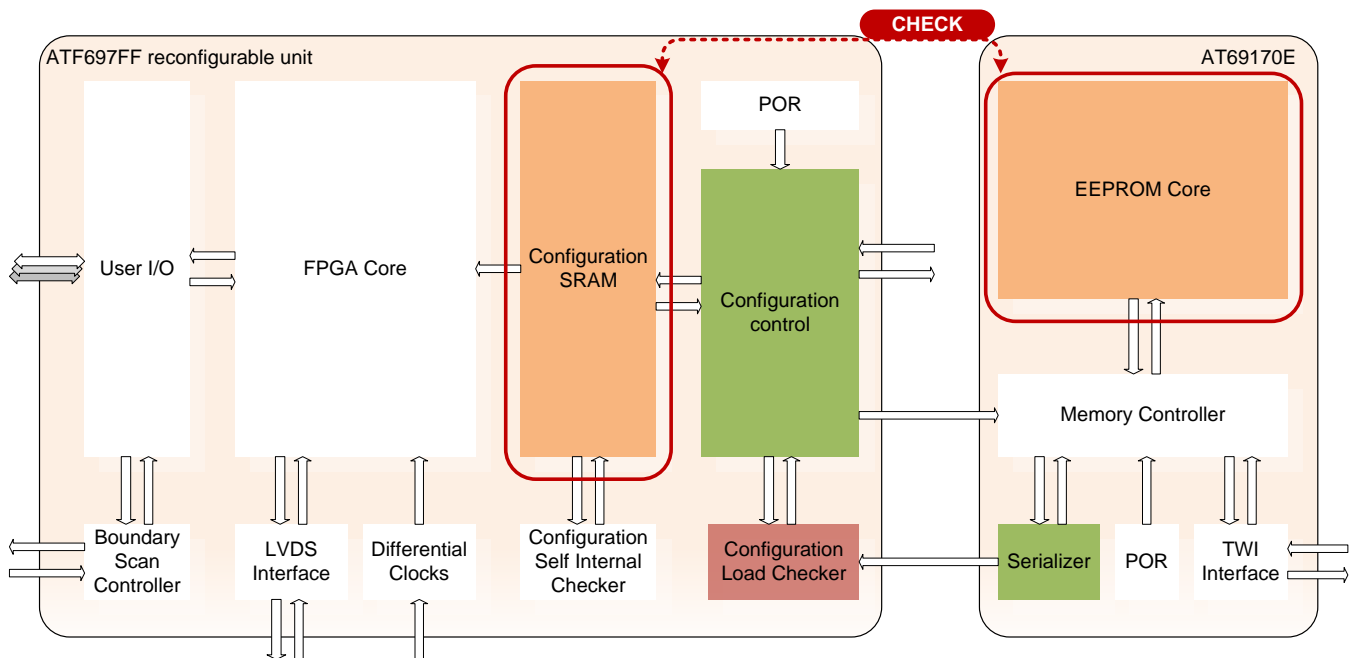

The ATF697FF reconfigurable unit, through the configuration logic embeds a feature called CHECK function. This feature, if activated, is useable at any time when the FPGA is in **Run** phase. It provides a strong mechanism to ensure that loaded data are the same than the EEPROM source one.

#### 11.3.1.1 Description

The following schematic represents an overview of the system made by the FPGA and a serial EEPROM memory. The highlighted modules show where the CHECK function takes place:

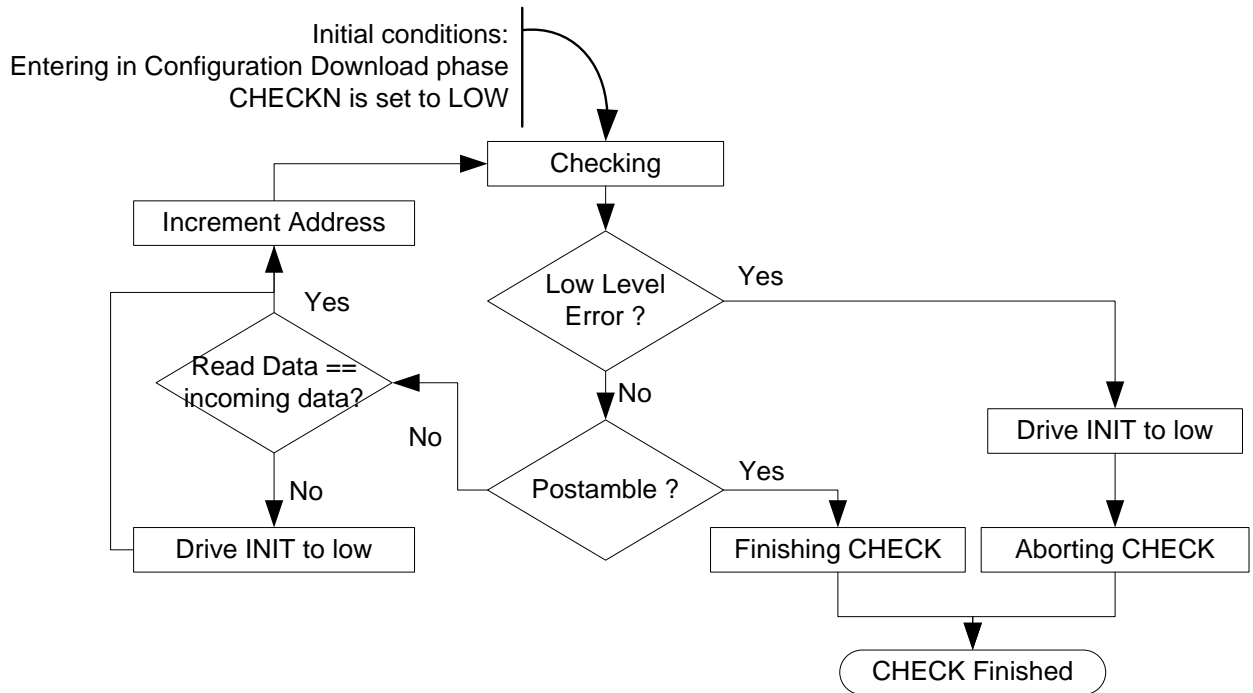

- The FGPA could be either in Mode 0, 1 or 7 for serial mode,
- The EEPROM has a serial interface for serial mode,
- The EEPROM interface is compliant with the interface required by the ATF697FF reconfigurable unit,
- The result of CHECK function reflects any differences between Configuration SRAM of ATF697FF reconfigurable unit and EEPROM memory content.

Figure 11-19. ATF697FF RECONFIGURABLE UNIT : CHECK function overview

The CHECK function obeys to the following workflow:

**Figure 11-20. ATF697FF reconfigurable unit CHECK function workflow**

To verify the data, the ATF697FF reconfigurable unit uses the CHECK function in parallel to a configuration download. The use of CHECK function is optional and can be bypassed by the user (Refer to Register Chapter for more details).

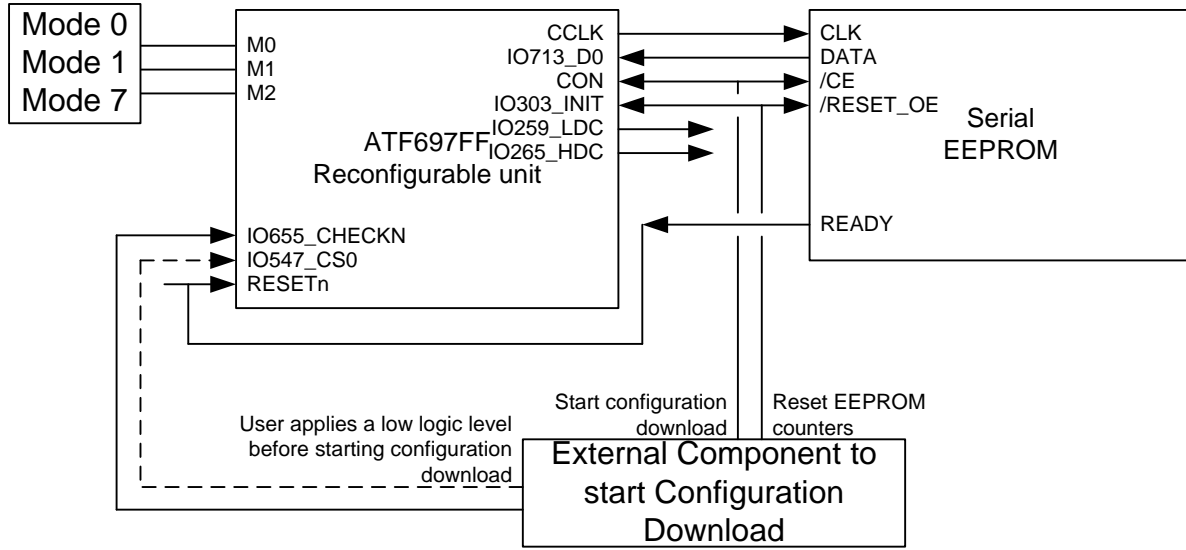

The differences between a nominal configuration download and a CHECK function is described below:

- When performing a configuration download, the “configuration control” module addresses the SRAM point and writes them as defined in the EEPROM bitstream,
- When performing a CHECK function, the “configuration control” module addresses the SRAM point, read them and compare their content to the value defined in the EEPROM bitstream,
- The “configuration load checker” module manages the protocol errors (low level errors) in the same way than for a configuration download, but checksums are not taken into account.

The following synoptics shows the required interface of ATF697FF reconfigurable unit for the use of CHECK function in serial modes. For each of these cases, the required interface is strictly the same than the one required for the configuration download but with the use of IO655\_CHECK\* pin.

### 11.3.1.2 Serial Modes

Figure 11-21. CHECK function in serial modes

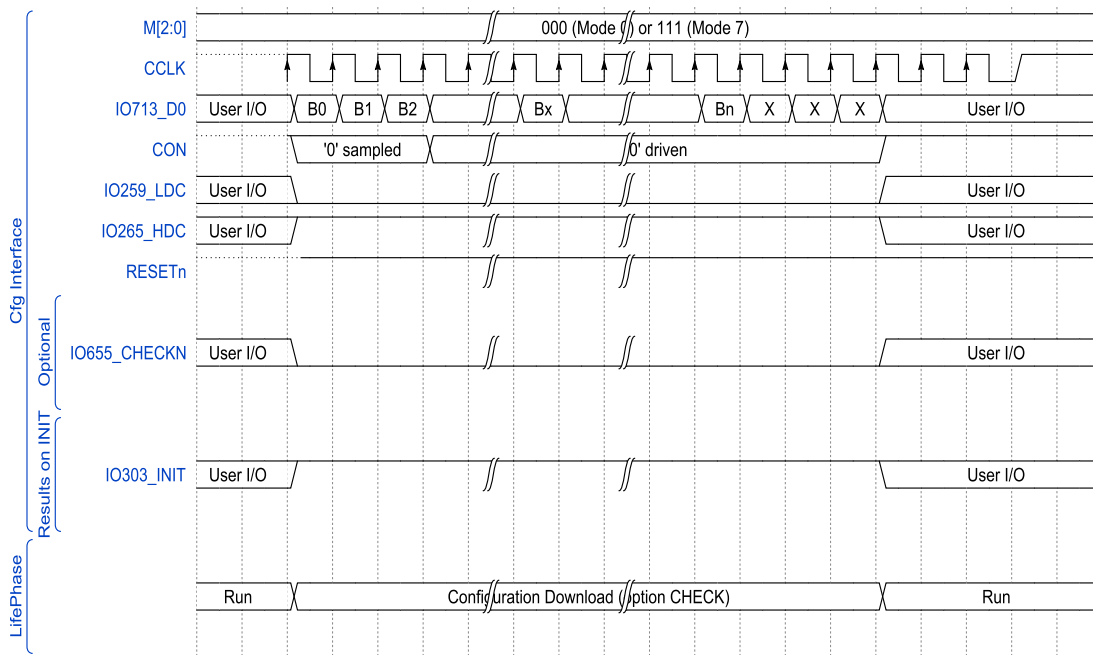

**Caution:** In serial mode, the required interface for CHECK function is the same than for configuration download. It means that for Mode 1, the IO547\_CS0 shall be used in parallel to the IO655\_CHECK\* pin when starting the configuration download (dotted line in figure above).

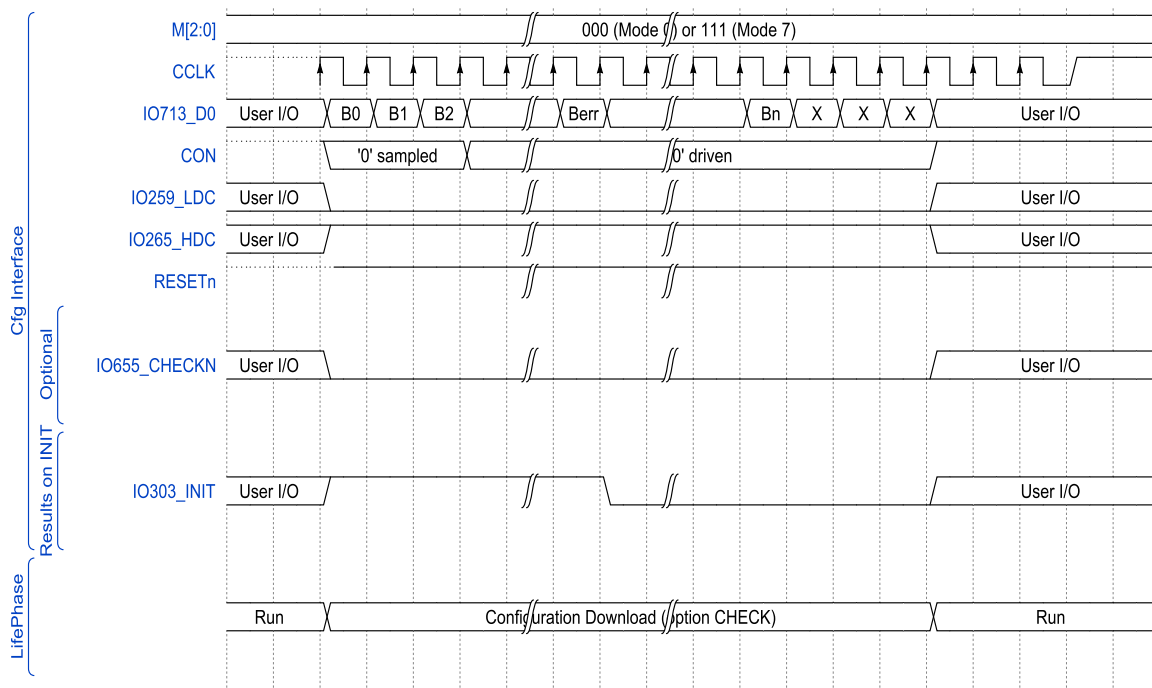

### 11.3.1.3 Behavior

The use of CHECK function is done by launching in **Run** lifephase a configuration download while IO655\_CHECK\* pin is externally driven to a low logic level.

Figure 11-22. ATF697FF reconfigurable unit CHECK function without error

**Figure 11-23. ATF697FF reconfigurable unit CHECK function with error**

**Caution:** It shall be noticed that in case of error detected during a CHECK function, two kinds of errors are possible:

- Low Level Error: the error that are protocol relevant and which bring the IO303\_INIT to be driven low after some CCLK periods,
- CHECK comparison mismatch: the signature is a drive to low of the IO303\_INIT two CCLK periods after the byte in default.

### 11.3.2 Self Integrity Checker function

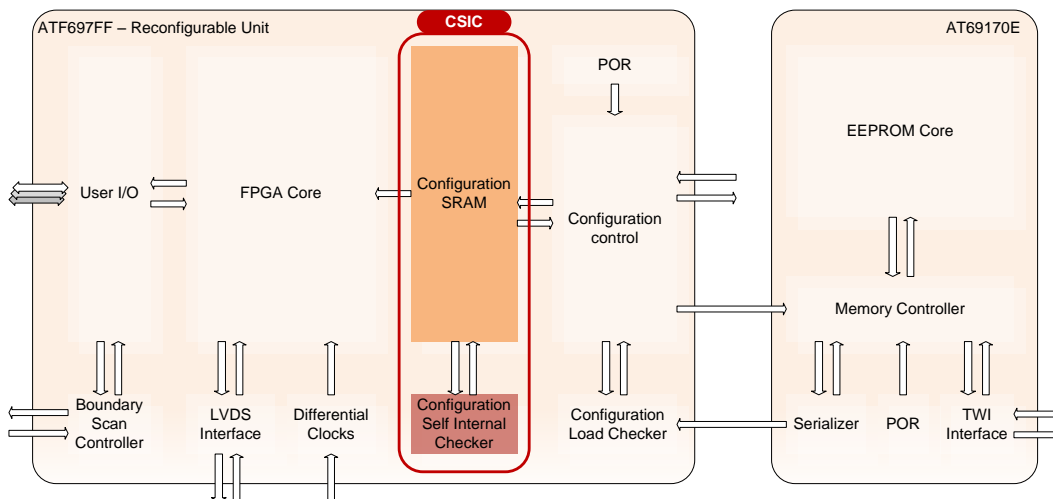

The ATF697FF reconfigurable unit, through the configuration logic embeds a feature called CSIC (for Configuration Self Integrity Checker). This feature, if activated, is useable in **Run** phase. It provides a strong mechanism to ensure the retention of the loaded data.

#### 11.3.2.1 Description

The following schematic represents an overview of the modules involved in the CSIC function:

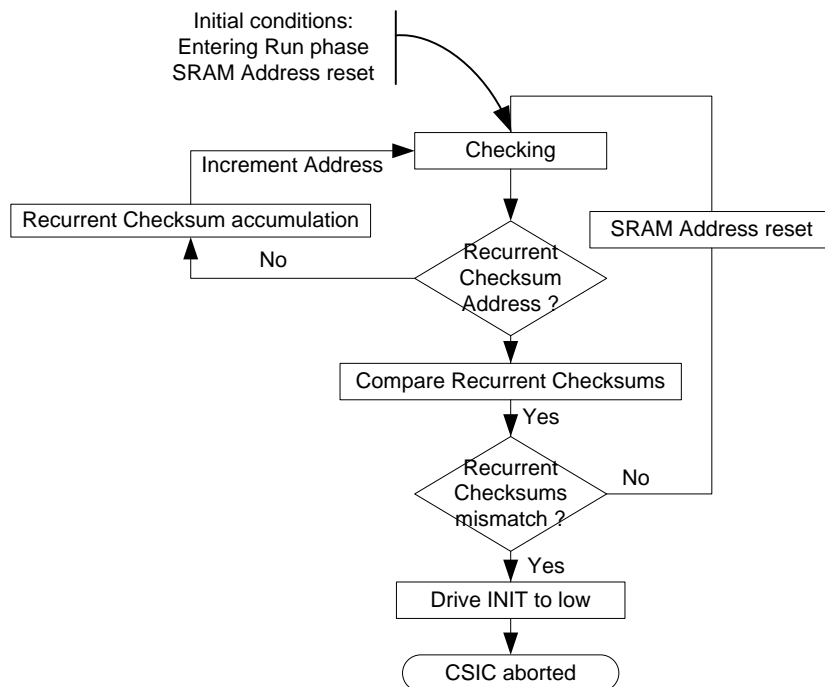

**Figure 11-24. ATF697FF reconfigurable unit CSIC Overview**

The CSIC function obeys to the following workflow:

**Figure 11-25. ATF697FF reconfigurable unit CSIC workflow**

The following points described how the CSIC function could be used and how it works:

- The CSIC function is not mode dependent and is activated with the bit CR8 of the configuration register (Refer to Register Chapter for more details),
- The bitstream will contain a window called “Recurrent Checksum” with a stored byte calculated by the IDS Software during the bitstream generation,
- The ATF697FF reconfigurable unit will calculate cyclically by the used of loaded data the value of this Recurrent Checksum and will compare the result with the one stored in the “Recurrent Checksum” window,

- In mode 0 (the only master mode), the CSIC function requires the activation of the bit CR13 of the configuration register (Refer to Register Chapter for more details). The continuous CCLK option is mandatory to clock the CSIC function,

**Caution:** CCLK will toggle during all the time of the Run phase.

- In all other modes (1 and 7), the CCLK shall be provided continuously after the configuration download by an external clock source. This continuous CCLK input is mandatory to clock the CSIC function,

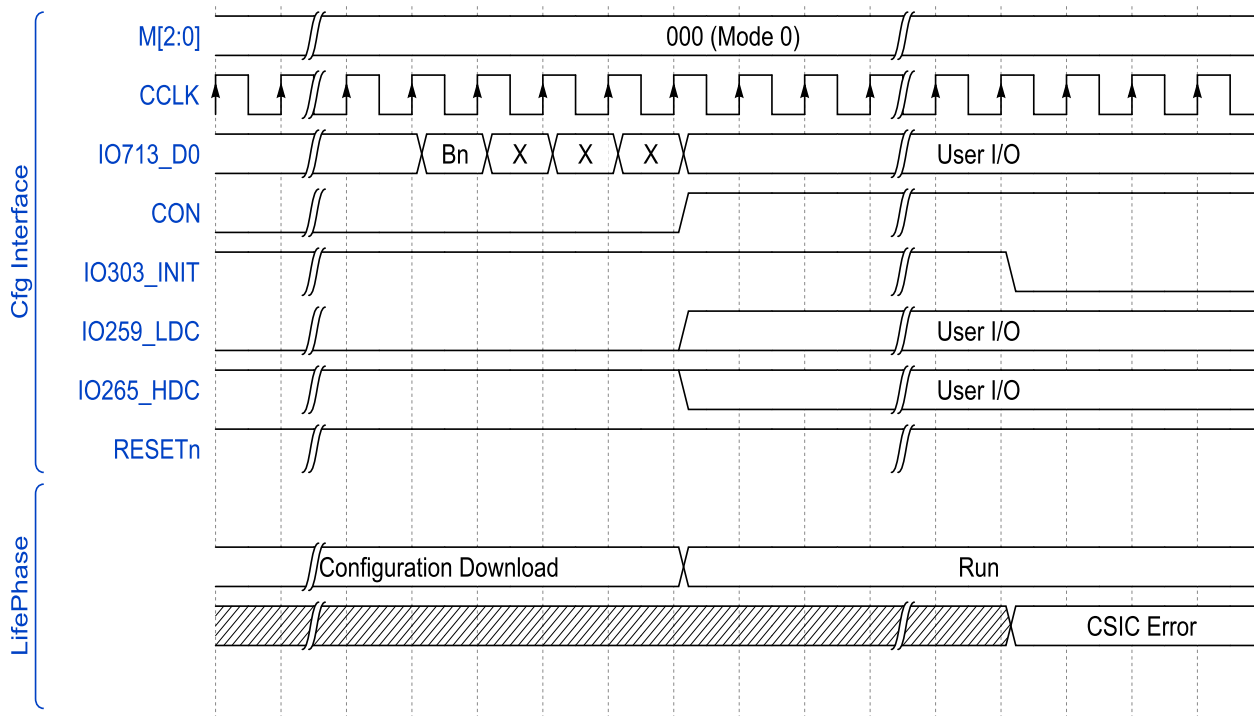

**Caution:** CCLK shall not be stop during all the time of the Run phase.

- When CSIC function is used, the IO303\_INIT pin remains in [CFG] function and is released to a high logic level while no error is detected. If a bit flips, it will bring the calculated recurrent checksum to be different from the stored recurrent checksum. The result will be a drive to low logic level of the IO303\_INIT until a Power-On Reset or a Manual Reset and the bitstream will continue to work.

**Caution:** IO303\_INIT will remain in [CFG] function during all the time of Run phase and shall be taken into account at system level.

### 11.3.2.2 Behavior

Figure 11-26. CSIC function behavior on error

## 11.4 FreeRam™

The ATF697FF reconfigurable unit offers 115Kbits of dual-port RAM called FreeRAM™. The FreeRAM™ is made of 32 x 4 dual-ported RAM blocks and dispersed throughout the array as shown in the figure hereafter. This FreeRAM™ is SEU hardened.

A 4-bit Input Data Bus connects to four horizontal local buses distributed over four sector rows. A 4-bit Output Data Bus connects to four horizontal local buses distributed over four sector rows. A 5-bit Input Address Bus connects to five vertical express buses in same column. A 5-bit Output Address Bus connects to five vertical express buses in same column. Ain (input address) and Aout (output address) alternate positions in horizontally aligned RAM blocks. For the left-most RAM blocks, Aout is on the left and Ain is on the right. For the right-most RAM blocks, Ain is on the left and Aout is tied off, thus it can only be configured as a single port. For single-ported RAM, Ain is the READ/WRITE address port and Din is the (bi-directional) data port.

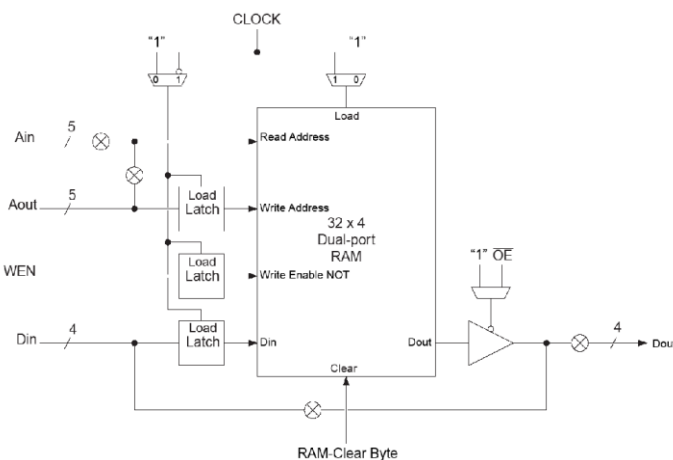

**Figure 11-27. FreeRam™ Block Interface**

Reading and writing of the 10ns 32 x 4 dual-port FreeRAM™ are independent of each other. Reading the 32 x 4 dual-port RAM is completely asynchronous. Latches on Write Address, Write Enable and Data In are transparent:

- when load is logic 1, data flows through
- when load is logic 0, data is latched.

**Figure 11-28. RAM logic - Detailed**

The latches are used to synchronize Write Address, Write Enable Not, and Din signals for a synchronous RAM.

Each bit in the 32 x 4 dual-port RAM is also a transparent latch. The front-end latch and the memory latch together form an edge-triggered flip flop. When a nibble is (Write) addressed and LOAD is logic 1 and WE is logic 0, data flows through the bit. When a nibble is not (Write) addressed or LOAD is logic 0 or WE is logic 1, data is latched in the nibble.

The two CLOCK muxes are controlled together; they both select CLOCK (for a synchronous RAM) or they both select "1" (for an asynchronous RAM). CLOCK is obtained from the clock for the sector-column immediately to the left and immediately above the RAM block.

## 12. Internal communication

### 12.1 Introduction

The ATF697FF reconfigurable processor embeds a full set of internal connectivity for control/command and data management between the two units:

- The complete external bus interface (EBI) is output from the ATF697FF device and also interconnected between the two units, allowing the use of the reconfigurable unit as a 'standard memory' mapped peripheral.
- The processor Host/Satellite PCI 2.2 compliant interface is shared between the two units has described here after
- A simple set of general purpose IO is also shared.

### 12.2 EBI sharing

Please refer to section "Memory Mapped Reconfigurable Unit" for details.

### 12.3 GPIO sharing

The GPIO0 to GPIO7 are shared internally between the processor and the reconfigurable unit. They are connected externally as well.

Here there is a table which summarizes the internal connexions for the GPIO part.

**Table 12-1. GPIO internal pin assignement**

ATF697FF pin name (processor side)	ATF697FF pin name (reconfigurable unit side)	ATF697FF pin direction (ATF697FF reconfigurable unit side)
GPIO0	IO233	Bi-directional
GPIO1	IO237	Bi-directional
GPIO2	IO331	Bi-directional
GPIO3	IO333	Bi-directional
GPIO4	IO337	Bi-directional
GPIO5	IO339	Bi-directional
GPIO6	IO343	Bi-directional
GPIO7	IO345	Bi-directional

### 12.4 PCI sharing

#### 12.4.1 Internal PCI interface: pin description

##### 12.4.1.1 PCI system

**PCI\_CLK** PCI clock (input)

This signal provides timing for all transactions on the PCI bus. All other PCI signals, except PCI\_RST\*, are sampled on the rising edge of PCI\_CLK and all other timing parameters are defined with respect to this edge.

**PCI\_RST\*** PCI Reset (input)

This active low input is used to bring PCI-specific registers, sequencers and signals to a consistent state. When asserted, it immediately halts and resets the PCI interface. The PCI interface resumes execution after the 5<sup>th</sup> rising edge of the PCI\_CLK clock after PCI\_RST\* was de-asserted.

**SYSEN\*** System Enable (input)

This active low input is used to configure the PCI interface as the Host-Bridge for the PCI bus (also called the System-Controller in a CompactPCI-compliant environment). If de-asserted, the PCI interface is configured as a satellite on the PCI bus.

This signal shall be kept static and free from glitches while the processor is operating, as it is not sampled internally. Changing the signal shall only be performed while the processor is under reset otherwise the processor's behavior is not predictable.

#### 12.4.1.2 PCI Address & Data

**A/D[31:0]** PCI Address Data (bi-directional)

Address and Data are multiplexed on the same PCI pins. During the address phase, A/D[31:0] contain a physical address (32 bits). For I/O, this is a byte address; for configuration and memory, it is a 32-bit address. During data phases, A/D[7:0] contain the least significant byte and A/D[31:24] contain the most significant byte.

**C/BE\*[3:0]** PCI Bus Command and Byte Enables (bi-directional)

During the address phase of a transaction, C/BE\*[3:0] define the bus command. During the data phase, C/BE\*[3:0] are used as Byte Enables. The Byte Enables are valid for the entire data phase.

**PAR** Parity (bi-directional)

This signal is even parity across A/D[31:0] and C/BE\*[3:0] (the number of "1"s on A/D[31:0], C/BE\*[3:0] and PAR equals an even number). The master drives PAR for address and write data phases; the PCI target drives PAR for read data phases.

#### 12.4.1.3 PCI Interface Control

**FRAME\*** Cycle PCI\_FRAME (bi-directional)

This signal is driven by the current master to indicate the beginning and duration of an access. FRAME\* is asserted to indicate a bus transaction is beginning. While FRAME\* is asserted, data transfers continue. When FRAME\* is deasserted, the transaction is in the final data phase or has completed.

**IRDY\*** Initiator Ready (bi-directional)

This signal indicates the initiating agent's ability to complete the current data phase of the transaction. IRDY\* is used in conjunction with TRDY\*. During a write, IRDY\* indicates that valid data is present on A/D[31:0]. During a read, it indicates the master is prepared to accept data.

**TRDY\*** Target Ready (bi-directional)

This signal indicates the target agent's (selected device's) ability to complete the current data phase of the transaction. TRDY\* is used in conjunction with IRDY\*. During a read, TRDY\* indicates that valid data is present on A/D[31:0]. During a write, it indicates the target is prepared to accept data.

**STOP\*** Stop (bi-directional)

This signal indicates the current target is requesting the master to stop the current transaction.

**LOCK\*** Lock (bi-directional)

This signal indicates an atomic operation to a bridge that may require multiple transactions to complete.

**IDSEL** Initialization Device Select (input)

Initialization Device Select is used as a chip select during configuration read and write transactions.

**DEVSEL\*** Device Select (bi-directional)

When actively driven, indicates the driven device has decoded its address as the target of the current access. As an input, DEVSEL\* indicates whether any device on the bus has been selected.

#### 12.4.1.4 PCI Arbitration

**REQ\*** PCI bus request (output)

This signal indicates to the arbiter that this agent desires use of the bus. This is a point-to-point signal. Every master has its own REQ\* which is tri-stated while PCI reset is asserted.

**GNT\*** PCI Bus Grant (input)

This signal indicates to the agent that access to the bus has been granted. This is a point-to-point signal. Every master has its own GNT\* which is ignored while PCI reset is asserted.

#### 12.4.1.5 PCI Error Reporting

**PERR\*** Parity Error (bi-directional)

This signal is only for the reporting of data parity errors during all PCI transactions except a Special Cycle. The PERR\* pin is sustained tri-state and must be driven active by the agent receiving data two clocks following the data when a data parity error is detected. The minimum duration of PERR\* is one clock for each data phase that a data parity error is detected.

**SERR\*** System Error (open-drain bi-directional)

This signal is for reporting address parity errors, data parity errors on the special cycle command, or any other system error where the result will be catastrophic. SERR\* is pure open drain and is actively driven for a single PCI clock by the agent reporting the error.

### 12.4.2 Internal PCI arbiter

The embedded PCI arbiter enables the arbitration of up to 4 PCI agents (numbered from 0 to 3). A round-robin algorithm is implemented as arbitration policy.

Since the PCI interface arbitration logic is not connected internally to the PCI arbiter, the REQ\* /GNT\* signals shall be connected externally to one of the AREQ\* []/AGNT\* [] pairs of the arbiter so the PCI interface is arbitered amongst the other agents on the bus.

The PCI interface can also be operated with an external PCI arbiter, thus not using the internal arbiter (the AREQ\* [3:0] input signals shall then be tied to a high level).

#### 12.4.2.1 Operation

An agent on the PCI bus requests the bus by driving low one of the AREQ\* [] signal. When the arbiter determines the bus can be granted to an agent, it drives low the corresponding AGNT\* [] signal.

The agent is only granted the PCI bus for one transaction. An agent willing further access to the bus shall continue to assert its AREQ\* [] line and wait to be granted the bus again.

#### 12.4.2.2 Policy

The arbitration policy is based on a round-robin algorithm with two nested priority loops. A high priority loop is defined as level 0, a low priority loop is defined as level <sup>1</sup>

Agents 0,1 and 2 can be individually configured to operate either on level 0 or on level 1 in the PCI Arbiter register (PCIA), whereas agent 3 operates on the fixed level 1 (low priority).

## Operation

The arbitration is performed by checking the AREQ\* [3:0] signals one after the other. In the first place, only agents with level 0 (high priority) are considered. If an agent asserts its AREQ\* [3] signal and the bus is not already granted, the corresponding AGNT\*[3] signal is driven low to grant the agent the bus. After a complete round-turn in level 0, a complete turn is done in level 1. The following figure illustrates the operation of the arbiter:

**Figure 12-1. Arbiter Operation**

Considering only agents submitting a request at the same time, the odds for being granted the bus can be summarized as follows:

- All agents in the same level have equal probability of grant
- All agents in level 1 have the same cumulated probability of grant as a single agent in level 0

## Re-arbitration

Re-arbitration occurs as soon as a transfer is finished and a new request is made (the PCI arbiter has internal knowledge of the FRAME\* signal) or when no agent is requesting the bus anymore (leading to bus parking).

**Caution:** No re-arbitration occurs during a transfer. Long bursts of one agent, even if assigned a low priority, can therefore significantly deteriorate the bandwidth available for other agents, especially the ones assigned a high priority.

**Caution:** In time critical systems, splitting long bursts into smaller chunks shall be considered as a way to favor re-arbitration more often.

## Bus Parking

As long as no bus request is active, the bus always remains granted (parked) to the last owner until another agent requests the bus.

After reset, the bus is automatically granted (parked) to agent 0.

### 12.4.3 PCI peripheral (ATF697FF processor's side)

#### 12.4.3.1 Overview

The PCI interface implementation is compliant with the PCI specification revision 2.2. It is a high performance 32-bit bus interface with multiplexed address and data lines. It is intended for use as an internal interconnect mechanism between the processor and the reconfigurable unit.

The PCI interface has initiator (master) and target capability, and data transfer can be in transmit or in receive direction from the processor to the reconfigurable unit.

The PCI bus can be operated at a frequency up to 33 MHz independently of the processor and the reconfigurable unit clock. The PCI clock domain and the processor clock domain are fully decoupled, allowing the others clocks to be faster, equal or slower than the PCI clock. Data transfer is through 4 synchronizing data FIFOs of 8 words each:

- MXMT: master/initiator-transmit-FIFO (from initiator to target)

- MRCV: master-receive-FIFO (from target to initiator)
- TXMT: target-transmit-FIFO (from target to initiator)
- TRCV: target-receive-FIFO (from initiator to target)

Depending on the configuration mode, the lower part of the PCI configuration registers can be accessed either locally in the register address space (address 0x80000100 to 0x80000144) or by another PCI device via the PCI bus with PCI configuration cycles and the IDSEL signal (the AT697 can never access its own configuration registers via the PCI bus). The upper part of the PCI configuration registers (0x80000148 to 0x80000178) and the PCI arbiter register PCIA (0x80000280) can only be accessed locally through the register address space. The configuration mode is selected by a hardware bootstrap on the SYSEN\* pin. The following two modes are available:

- Host-Bridge (SYSEN\* = 0)

In host-bridge mode, the PCI registers at address 0x80000100 to 0x80000144 are only accessible locally by the processor, but not through the PCI bus. The host-bridge is sometimes also called System Controller, it controls other satellite devices through PCI configuration commands.

- Satellite (SYSEN\* = 1)

In satellite mode, the lower part of the processor PCI registers can be written and read by another PCI device (the host-bridge) using PCI configuration cycles, whereas the local registers addresses 0x80000100 to 0x80000144 are read-only.

The state of the SYSEN\* pin is available internally (PCIIS.sys) to enable a boot software to load the appropriate driver(s).

Some other features are supported by this interface like:

- Target lock
- Target zero-latency fast back-to-back transfers
- Zero wait-state burst mode transfers
- Memory read line/multiple
- Memory write and invalidate
- Delayed read
- Flexible error reporting by polling

#### 12.4.3.2 PCI Initiator (Master)

PCI initiator transactions are issued by the processor either as memory-mapped load/store instructions or as DMA-assisted data transfers between the PCI bus and the local memory.

Load/store instructions to a memory address in the PCI area (0xA0000000 0xFFFFFFFF) are automatically translated by the interface into the appropriate PCI transaction. Any PCI address outside of this range can only be accessed via a DMA-assisted data transfer.

The PCI initiator (memory-mapped or DMA-assisted) is enabled by setting bits PCISC.com2 and PCIIC.mod.

### Memory-Mapped Access

Instructions of different width (byte, half-word, word or double-word) can be performed for each address of the PCI address range. The three least-significant bits of the address (A/D[2:0]) are used to determine which PCI byte-enable signals (C/BE\*[3:0]) should be active during the transaction.

According to the SPARC architecture, big-endian mapping is implemented where the most significant byte standing at the lower address (0x..00) and the least significant byte standing to the upper address (0x..03).

Writing a byte to a PCI word-aligned address ( $A/D[1:0] = 00$ ) results in the byte-enable pattern ( $C/BE*[3:0] = 0111$ ) indicating the most significant byte lane ( $A/D [31:24]$ ) of the PCI data bus is selected.

For all sub-word load instructions using a PCI memory command, the byte enables are all-0s, assuming reading more bytes than necessary has no side effects on a prefetchable target. Non-prefetchable targets where exact read byte-enables are required should be accessed with PCI I/O commands.

Byte, half-word and word size load/store instructions are translated into a single word PCI transaction with the appropriate byte-enable pattern, while a double-word load/store instruction are translated into a 2-word burst PCI transaction.

The following table presents the mapping between instructions and PCI byte enables generated for memory write and I/O read/write commands:

**Table 12-2. Byte-Enable<sup>1</sup> vs Instruction**

Bit Width	8	16	32	64
Instruction	LDSB, LDUB, STB	LDSH, LDUH, STH	LD, ST	LDD, STD
$Ai[2:0]=000^4$	0111	0011	0000	0000 <sup>2</sup>
$Ai[2:0]=100^4$				$n/a^3$
$Ai[1:0]=01^4$	1011	$n/a^3$	$n/a^3$	$n/a^3$
$Ai[1:0]=10^4$	1101	1100	$n/a^3$	$n/a^3$
$Ai[1:0]=11^4$	1110	$n/a^3$	$n/a^3$	$n/a^3$

Note: 1.PCI byte-enables signals are active low ( $C/BE*[3:0]$ )

Note: 2.Operation is performed as a single data burst transaction

Note: 3.Improperly aligned access is cancelled and causes a `mem_address_not_aligned` trap (0x07)

Note: 4.Ai is the source/destination memory address referenced by the load/store instruction

### Command Type

The PCI command type to be used for memory-mapped transactions is set in `PCIIC.cmd` to one of IO-read/write, memory-read/write (default after reset), configuration-read/write(caution) or memory-read-line/write-invalidate.

Memory commands are issued on the PCI bus with the 2 least significant bits of the address cleared ( $A/D [1:0] = 00$ ) to indicate the linear incrementing mode is being used.

Configuration(caution) and I/O commands are issued on the PCI bus with the address unchanged.

**Caution:** Configuration transactions shall only be generated in host-bridge mode (`SYSEN*` pin tied to a low level).

### Operation

1. To engage memory-mapped transactions on the PCI interface:
2. Enable PCI initiator mode (`PCISC.com2 = 1`) and memory-mapped transactions (`PCIIC.mod = 1`).
3. Clear the PCI interrupt pending register (`PCIITP = 0xF0`).
4. In interrupt-assisted operation, enable any of the 4 possible PCI interrupt sources: `SERR*` asserted (`PCIITE.SERR* = 1`), initiator parity error (`PCIITE.iper = 1`), initiator fatal error (`PCIITE.ife = 1`) and/or initiator internal error (`PCIITE.iier = 1`). Interrupts shall be enabled as well in the processor (`PSR.et = 1` and `PSR.pil < 14`) and the interrupt controller (`ITMP.imask[14] = 1`).

5. The interrupt service routine (ISR) shall check the PCI interface status: SERR\* asserted (PCIITP.SERR\* = 1), initiator parity error (PCIITP.iper = 1), initiator fatal error (PCIITP.ife = 1) or initiator internal error (PCIITP.iier = 1) and clear each bit in software by rewriting a 1 as appropriate so further events can be detected.
6. Select the appropriate PCI command type (PCIIC.cmd).
7. Execute a load/store instruction on a local memory address mapped in the PCI address range (0xA0000000 to 0xFFFFFFFF).
8. If not using interrupts, check the PCI interface status: SERR\* asserted (PCIITP.SERR\* = 1), initiator parity error (PCIITP.iper = 1), initiator fatal error (PCIITP.ife = 1) and/or initiator internal error (PCIITP.iier = 1) then clear each bit as appropriate (in software by rewriting a 1) so further events can be detected.
9. Repeat steps 5 to 6 as many times as needed.
10. Repeat steps 4 to 7 as many times as needed with a new PCI command type.

## Limitations

The following PCI features are not supported:

- PCI interrupt acknowledge, special cycles and memory read-multiple
- 64-bit addressing and Dual Address Cycles (DAC)
- Cacheline wrap mode with memory commands
- PCI power management.
- Master fast back-to-back transactions

## Direct Memory Access

A DMA controller is available to perform data transfers between the local memory and a remote target on the PCI bus.

The processor needs only initiate the transfer by programming the DMA controller. Once programmed, the DMA controller is fully autonomous and performs data transfers in the background while the processor is running. Interrupts are provided for synchronization.

The DMA controller only performs word transfers with all 4 PCI byte-lanes enabled (C/BE\*[3:0]= 0000).

## Operation

To engage DMA-assisted transactions on the PCI interface:

1. Enable PCI initiator mode (PCISC.com2 = 1) and DMA-assisted transactions (PCIIC.mod = 1).
2. Clear the PCI interrupt pending register (PCIITP = 0xF0).
3. In interrupt-assisted operation, enable any of the 5 possible PCI interrupts sources: DMA transfer finished (PCIITE.dmaf = 1), SERR\* asserted (PCIITE.PCI\_SERR = 1), initiator parity error (PCIITE.iper = 1), initiator fatal error (PCIITE.ife = 1) and/or initiator internal error (PCIITE.iier = 1). Interrupts shall be enabled as well in the processor (PSR.et = 1 and PSR.pil < 14) and the interrupt controller (ITMP.imask[14] = 1).
4. The interrupt service routine (ISR) shall check the PCI interface status: DMA transfer finished (PCIITP.dmaf = 1), SERR\* asserted (PCIITP.SERR\* = 1), initiator parity error (PCIITP.iper = 1), initiator fatal error (PCIITP.ife = 1) and/or initiator internal error (PCIITP.iier = 1) then clear each bit as appropriate (in software by rewriting a 1) so further events can be detected.
5. Define the start address in the PCI address space (PCISA).
6. Define in a single write operation the PCI command and the number of words to be transferred (PCIDMA.cmd and PCIDMA.wcnt, 1 to 255 words). At this point for PCI read-based transactions, the PCI interface starts pre-fetching data from the PCI remote target.
7. Define the start address in local memory (PCIDMAA). At this point, data transfer starts in local memory.
8. Wait (interrupt or poll) for the transfer to finish (PCIITP.dmaf = 1).

9. If not using interrupts, check the PCI interface status: SERR\* asserted (PCIITP.SERR\* = 1), initiator parity error (PCIITP.iper = 1), initiator fatal error (PCIITP.ife = 1) and/or initiator internal error (PCIITP.iier = 1) then clear each bit as appropriate (in software by rewriting a 1) so further events can be detected.
10. Repeat steps 4 to 8 as many times as needed.

## Limitations

The following limitations shall be considered when using the DMA controller:

- Memory-mapped access and DMA are mutually exclusive: any load/store instruction to the PCI area in local memory (0xA0000000 0xFFFFFFFF) during a DMA transfer will stall the processor until the DMA transfer is completed.
- Moreover, a PCI memory-mapped access (like in an interrupt service routine) which occurs during the initiate procedure of the DMA transfer (between steps 3 to 5) will cause a deadlock requiring a reset of the processor. The application shall ensure the atomicity of steps 4 to 6.
- A wrong DMA initialization sequence may cause the DMA state machine to lock and report an error (PCIITP.iier = 1). The PCI interface shall then be reset (PCIIC = 0xFFFFFFFF).
- A DMA transfer cannot cross a 256 words aligned segment boundary in local memory. If the combination of the start address (PCISA) and the number of words to be transferred (PCIDMA.wcnt) is to cross that boundary, the DMA controller will terminate the transfer by the end of the segment (PCIITP.dmaf = 1), flush the FIFOs and report an error (PCIITP.iier = 1).
- A DMA transfer cannot operate within the PCI memory-mapped address range in local memory. If the local address of a DMA transfer lies in the PCI memory-mapped address range (0xA0000000 0xFFFFFFFF), the DMA controller will cancel the transfer and report an error (PCIITP.iier = 1).

## Configuration

Access to a PCI target configuration address space requires the target device to be selected at its IDSEL pin. In many systems, the IDSEL pins of the satellite devices are directly connected to one of the A/D [31:11] signals.

### Memory-Mapped

Because of the local memory address range limitation (0xA0000000 to 0xFFFFFFFF), the remote target IDSEL signal shall only be connected to lines from A/D [29:11]. This allows up to 19 PCI targets to be configured: the target connected to A/D [29] is selected with address 0xE000xxx, A/D [28] with address 0xD000xxx, A/D [27] with address 0xC800xxx, A/D [26] with address 0xC400xxx and so on.

### DMA-Assisted

Any target connected to A/D [31:11] can be configured with the DMA controller.

### 12.4.3.3 PCI Target

PCI target transactions originate from remote PCI initiators (masters) to the PCI interface.

The processor needs only configure the interface by programming the target controller. Once programmed, the target controller is fully autonomous and performs data transfers in the background while the processor is running. Interrupts are provided for synchronization.

## Interface Setup

The target interface is programmed as follows<sup>1</sup>:

- Enable/Disable<sup>1</sup>. parity error checks on the PCI interface (PCISC.com6).
- Enable/Disable<sup>12</sup> remote access to target Memory Space (PCISC.com1).
- If enabled, set<sup>1</sup> the base address to each 16 MB target memory area in the PCI address space (MBAR1.badr & MBAR2.badr) and in local memory (PCITPA.tpa1 & PCITPA.tpa2).
- Enable/Disable<sup>12</sup> remote access to target I/O Space (PCISC.com0).

- If enabled, set<sup>1</sup> the base address to the 1024 bytes target I/O area in the PCI address space (IOBAR3.badr). Base address in local memory is not programmable (PCITPA.tpa<sup>3</sup>) and is mapped to the AT697 configuration registers (0x80000000 0x80000400).
- Enable/Disable the storage in local memory of remote data received with PCI parity error (PCITSC.rfpe). If disabled, data received with a parity error will be discarded.

Note: 1.The PCI configuration registers with writable bits (PCISC, PCIBHLC, MBAR1, MBAR2, IOBAR3, PCILI, PCIIRT & PCICW) can only be programmed by the processor when in Host-Bridge mode (SYSEN\* = 0), while they can only be programmed by the remote host-bridge when in Satellite mode (SYSEN\* = 1).

Note: 2.The other PCI target registers (PCITSC & PCITPA) are always and only accessible by the processor.

Note: 3.At least one of target Memory Space (PCISC.com1) and target I/O Space (PCISC.com0) shall be enabled for target operation

**Caution:** If the PCI target is to share any data with the processor while the data cache is active (CCR.dcs = 01 or 11), care shall be taken to first enable the data cache snoop (CCR.ds = 1) or flush the data cache (CCR.fd = 1) when appropriate.

**Caution:** If the PCI target is to provide any instruction to the processor to execute while the instruction cache is active (CCR.ics = 01 or 11), care shall be taken to flush the instruction cache (CCR.fi = 1) when appropriate.

## Limitations

The following limitations shall be considered when using the PCI target:

- The PCI target cannot operate within the PCI memory-mapped address range in local memory. If the programmed target local address (PCITPA) lies in the PCI memory-mapped address range (0xA0000000 0xFFFFFFFF), the target controller will cancel the transfer and report an error (PCIITP.tier = 1).
- Target read transactions assume the target space to be prefetchable (reading from an address does not alter the data) and target Memory Read and I/O Read commands are generally prefetched.
- The target controller prefetches up to 8 words into the transmit FIFO once the target read address is available. After the last required data word is transferred to the PCI interface, the FIFO is automatically flushed to discard any unused prefetched data.
- This behavior shall be considered if a non-prefetchable device (like a UART) is to be read through the PCI target interface.
- The interface supports the following PCI write byte-enable patterns (C/BE\*[3:0]): single-byte (0111, 1011, 1101 & 1110), half-word (0011 & 1100), word (0000) and ignore-data (1111, frequently used as a dummy write cycle). A data received with any other byte-enable pattern is discarded and an error is reported (PCIITP.tber = 1).

## Delayed-Read

As specified in the PCI standard, delayed-read functionality is implemented as follows:

- When a read request was retried (because data from local memory is not available yet), the interface remains locked for any other target read (targeting different addresses). The initiator of the original read is expected to later repeat the request to the same address.
- A delayed-read can however be interrupted by one or more PCI write accesses. The PCI standard requires each write command to be processed first so to prevent a system lock-up.
- Meanwhile, the interface prefetches read-data from local memory into the target-transmit FIFO (TXMT). When the read request is repeated (after the interfering write, if any), the requested data is available in the FIFO and the delayed-transfer completes normally.

#### 12.4.3.4 PCI Error Reporting

Parity check, parity error signal (PERR\*) and system error signal (SERR\*) are implemented as foreseen by the PCI standard. They can be controlled in the combined PCI Command & Status register (PCISC).

In addition, PCI initiator and PCI target error conditions and status information are always reported<sup>1</sup> in PCIITP (PCI Interrupt Pending).

If also enabled in PCIITE (PCI Interrupt Enable), each error condition or status information set by the PCI core in PCIITP will trigger the PCI interrupt (ITP.ipend[14] = 1) if enabled in the interrupt controller (ITMP.imask[14] = 1). Interrupts shall then be enabled as well in the processor (PSR.et = 1 and PSR.pil < 14) so the event can be handled.

For testing purpose, the error condition and status information can also be forced in PCIITP by setting the corresponding bit in PCIITF (PCI Interrupt Force).

Note: 1. These bits are never cleared in hardware and shall be cleared in software (by rewriting a 1) so new events can later be registered.

Status information of the various data FIFOs and state machines is available in PCIIS (PCI Initiator Status) and PCITSC (PCI Target Status). It is recommended to check these registers for idle state when configuring the PCI interface and before performing any transaction. Non-nominal values may indicate a previous transaction was not properly completed and spurious data possibly remains in the FIFOs. In such a case, the PCI initiator interface shall be reset (PCIIC = 0xFFFFFFFF) and/or the PCI target interface shall be reset (PCITSC.cs = 0xF), its FIFOs flushed (PCITSC.xfe = 1 and/or PCITSC.rfe = 1) and the transaction aborted (PCITSC.xff = 1).

#### 12.4.3.5 PCI Data Rate

During PCI initiator and target transfers, the interface tries PCI burst transactions whenever possible to approach the theoretical PCI data rate (~1 Gbit/s at 33 MHz).

However, the exact scheduling of PCI transactions depends on so many factors (clock ratio between PCI and processor, PCI bus traffic, PCI arbitration, processor internal bus activity, wait-states on external memory & I/O peripherals...) there is no guarantee for a sustained burst. The effective data rate may even be far below the theoretical performance in some specific situations.

For a reasonable performance:

- the processor clock frequency should be at least 3 times the PCI clock frequency
- processor accesses to slow devices (IO or memory with high wait-states) should be minimized

#### 12.4.3.6 Disabling the PCI

In applications where the PCI function is not used, the PCI\_CLK and the PCI\_RST\* pin shall be tied to a low level. As a consequence, all bidirectional PCI pins including the bus request pin REQ\* are tri-stated so they shall be driven to a valid high/low level with a pull-up/down to prevent them from floating. When the PCI arbiter is not used, the AREQ\*[3:0]input signals shall be tied to a high level.

### 12.4.4 PCI Interface

The whole PCI signals shared between the ATF697FF processor and the ATF697FF reconfigurable unit are listed next.

**Table 12-3. PCI interface shared signals**

Processor Pin name	Reconfigurable unit Pin Name	Reconfigurable unit Pin direction	Processor Pin name	Reconfigurable unit Pin Name	Reconfigurable unit Pin direction
A/D[0]	IO137	Bi-directional	A/D[30]	IO227	Bi-directional
A/D[1]	IO139	Bi-directional	A/D [31]	IO231	Bi-directional
A/D[2]	IO143	Bi-directional	AGNT*[0]	IO245	Input, pull up enable
A/D[3]	IO145	Bi-directional	AGNT*[1]	IO247	Input, pull up enable
A/D[4]	IO147	Bi-directional	AGNT*[2]	IO251	Input, pull up enable
A/D[5]	IO151	Bi-directional	AGNT*[3]	IO253	Input, pull up enable
A/D[6]	IO153	Bi-directional	AREQ*[0]	IO257	Output, pull up enable
A/D[7]	IO157	Bi-directional	AREQ*[1]	IO263	Output, pull up enable
A/D[8]	IO159	Bi-directional	AREQ*[2]	IO267	Output, pull up enable
A/D[9]	IO163	Bi-directional	AREQ*[3]	IO271	Output, pull up enable
A/D[10]	IO165	Bi-directional	C/BE*[0]	IO273	Bi-directional
A/D[11]	IO167	Bi-directional	C/BE*[1]	IO277	Bi-directional
A/D[12]	IO171	Bi-directional	C/BE*[2]	IO279	Bi-directional
A/D[13]	IO173	Bi-directional	C/BE*[3]	IO283	Bi-directional
A/D[14]	IO175	Bi-directional	PCI_CLK	IO285	Output
A/D[15]	IO177	Bi-directional	DEVSEL*	IO287	Bi-directional
A/D[16]	IO180	Bi-directional	FRAME*	IO291	Bi-directional
A/D[17]	IO185	Bi-directional	GNT*	IO293	Output
A/D[18]	IO187	Bi-directional	SYSEN*	IO297	Output
A/D[19]	IO191	Bi-directional	IDSEL	IO299	Output
A/D[20]	IO193	Bi-directional	IRDY*	IO305	Bi-directional
A/D[21]	IO197	Bi-directional	LOCK*	IO307	Bi-directional
A/D[22]	IO199	Bi-directional	PAR	IO311	Bi-directional
A/D[23]	IO203	Bi-directional	PERR*	IO313	Bi-directional
A/D[24]	IO205	Bi-directional	REQ*	IO317	Input
A/D[25]	IO207	Bi-directional	PCI_RST*	IO319	Output
A/D[26]	IO213	Bi-directional	SERR*	IO323	Bi-directional
A/D[27]	IO217	Bi-directional	STOP*	IO325	Bi-directional
A/D[28]	IO219	Bi-directional	TRDY*	IO327	Bi-directional
A/D[29]	IO223	Bi-directional			

**Caution:** Warning: These shared IO have to be correctly configured to avoid signal reflexions and damages on the IOs of the ATF697FF component.

#### 12.4.5 To launch an internal PCI transaction between the processor and the reconfigurable unit

- The IO285 signal should be configured in output and generate the 33 MHz PCI\_CLK clock.
- The whole PCI agents should be configured as Host bridge or as Satellite:
  - To configure the processor as a HOST, IO297 should be in output mode, driven at '0'. The reconfigurable unit is configured in SATELLITE, as returns.
  - To configure the processor as a SATELLITE, IO297 should be in output mode, driven at '1'. The reconfigurable unit is configured in HOST, as returns.
- The HOST should launch an identification to determine the other agents existing on the PCI bus.
- The HOST should program the configuration space of the PCI satellite device.  
At this state, the network is configured.
- The initiator could now launch a transaction in memory mapped (MM) or in Direct Memory Access (DMA) mode on the PCI bus.
- The target will respond to the PCI transaction.

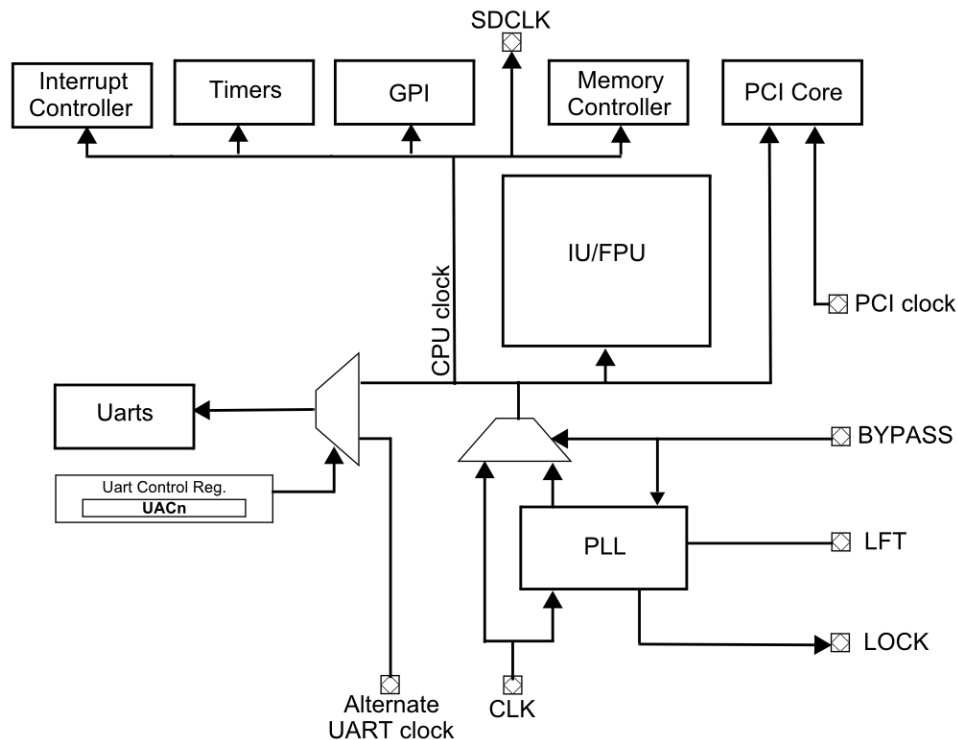

## 13. Clock system

### 13.1 Clock: processor part

#### 13.1.1 Overview

The ATF697FF processor operates two clocks domains: the CPU clock and the PCI clock. The following figure presents the clock system of the processor and its distribution.

Figure 13-1. Clock Distribution

Note: The PLL is powered-down when the BYPASS signal is asserted.

#### 13.1.2 PCI Clock

The PCI clock is dedicated to the PCI Interface. It is used in particular by the PCI wrapper that shares its activity between the two clock domains.

##### 13.1.2.1 External Clock

The PCI interface and its associated wrapper can only be driven from an external clock. The PCI clock shall be connected to the PCI\_CLK pin of the PCI interface. This input shall be driven at a frequency in the range of 0 up to 33 MHz.

#### 13.1.3 CPU Clock

The CPU clock is routed to the parts of the system concerned with operation of the SPARC core. Examples of such modules are the CPU core itself, the register files... The CPU clock is also used by the majority of the I/O modules like Timers, Memory controller, Interrupt Controller, with the exception of the PCI Interface.

The CPU clock is driven either directly by an external oscillator or by the internal PLL.

### 13.1.3.1 External Clock

To drive the device directly from an external clock source, the CLK input shall be driven by an external clock generator while the BYPASS pin is driven high. In that way, the CPU clock is the direct representation of the clock applied to CLK.

When the external CPU clock source is selected, the clock input can be driven at a frequency in the range of 0 MHz up to 100 MHz.

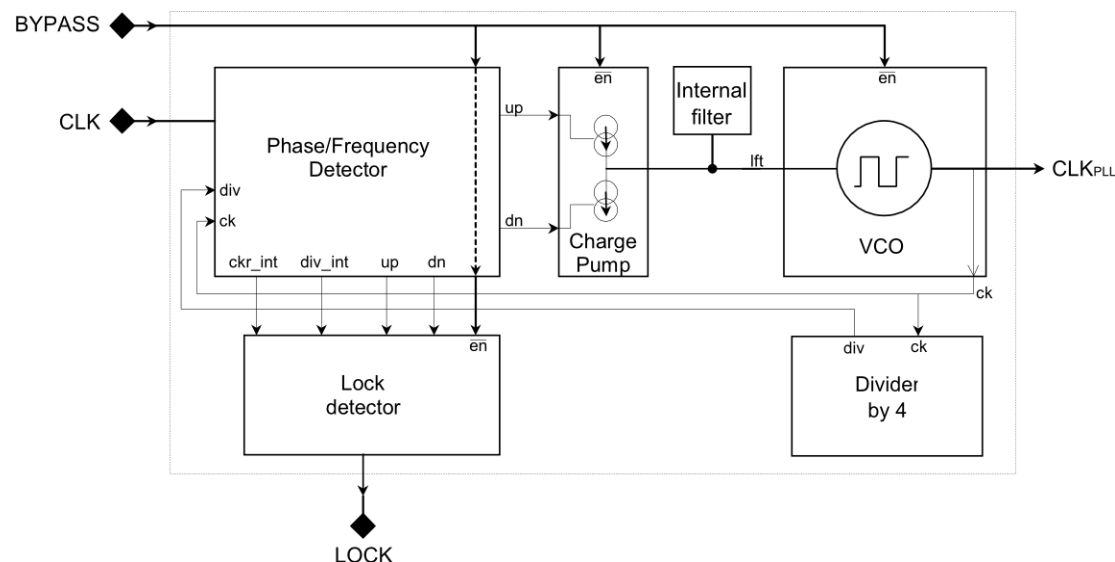

### 13.1.3.2 PLL

The CPU clock can be issued from the internal PLL.

## Overview

The PLL contains a phase/frequency detector, charge pump, voltage control oscillator, low-pass filter, lock detector and divider.

Figure 13-2. PLL Block Diagram

The PLL implemented is configured in hardware to provide an internal clock frequency of four times the frequency of the input clock.

## PLL control

The PLL control is performed in hardware through dedicated pins.

The following table presents the assignment and functions of the PLL control pins.

Table 13-1. PLL Ports Description

Pin name	Function
LOCK	The PLL is locked and delivers the expected internal clock
CLK	External clock input

Pin name	Function
BYPASS	Bypass the internal PLL and directly drive the internal clock from CLK

## Operation

To drive the device from the internal PLL, the CLK input shall be driven by an external clock generator while the BYPASS pin is driven low. That way, the CPU clock frequency is four times the frequency of the clock applied to CLK.

When the PLL is enabled, the CLK clock input shall be driven at a frequency in the range of 18 MHz up to 25 MHz.

### 13.1.4 Fault-Tolerance & Clock

To protect against SEU errors (Single Event Upset), each on-chip register is implemented using triple modular redundancy (TMR).

Moreover, an independent clock tree is used for each of the three registers making up one TMR module. This feature protects against SET errors (Single Event Transient) in the clock tree, to the expense of increased routing.

The CPU clock and the PCI clock are built as three-clock trees.

To prevent erroneous operations from single event upset (SEU) errors and single event upset (SEU), the ATF697FF processor is based on full triple modular redundancy (TMR) architecture.

Figure 13-3. TMR structure

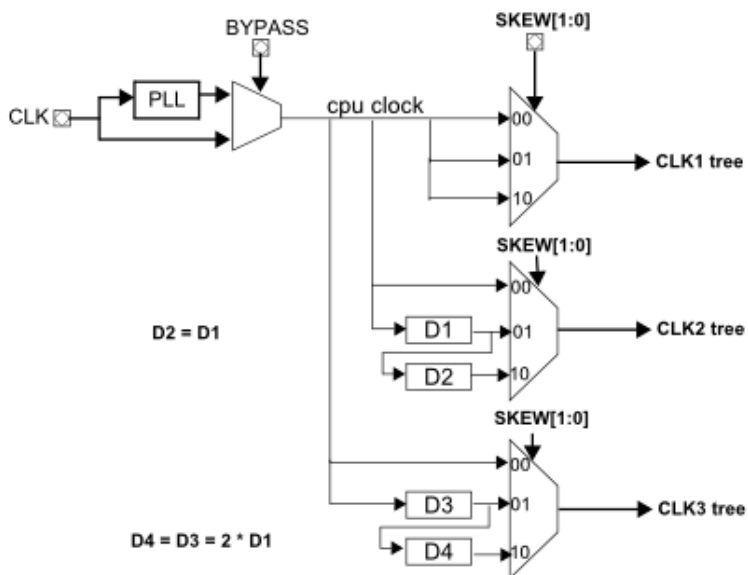

Such architecture is based on a fully triplicated clock distribution (CLK1, CLK2 and CLK3). In that way, each one of the PCI clock and the cpu clock are build as three-clock trees.

#### 13.1.4.1 Skew

To prevent the processor from corruption by SET errors (Single Event Transient), skew can be programmed on the clock trees. The two dedicated pins SKEW[1:0] are used to control the skew on the clock trees.

Here is a short description of the skew implementation:

Figure 13-4. CPU clock tree overview

Three configurations are available:

- natural skew (SKEW[1:0] = 00), this is the standard clock-tree as routed internally
- medium skew (SKEW[1:0] = 01), the 3 clock-trees are shifted away in time one from each other
- maximum skew (SKEW[1:0] = 10), the 3 clock-trees are further shifted away in time

Table 13-2. SKEW Assignments

SKEW[1:0]	DELAY		Comments
	CLK1 -> CLK2	CLK1 -> CLK3	
00	natural	natural	natural skew
01	D1	D3	medium skew
10	D1 + D2	D3 + D4	maximum skew
11	reserved (shall not be used)		

Note: Medium skew and maximum skew configurations improve SET protection but lead to reduced operating performance: maximum clock frequency is reduced and timings are slower than when configured for natural skew (see "Electrical Characteristics").

## 13.2 Clock: reconfigurable unit part

The ATF697FF reconfigurable unit clock system consists in a fully SET hardened clocking scheme. It provides user with two types of clock

- 8 Global Clocks
- 1 Fast Clocks : FCK3 – FCK4 (the both clocks are multiplexed.)

Each column of an array has a “Column Clock mux” and a “Sector Clock mux”. The Column Clock mux is at the top of every column of an array and the Sector Clock mux is at every four cells. The Column Clock mux is selected from one of the eight Global Clock buses. The clock provided to each sector column of four cells is inverted, non-inverted or tied off to “0”, using the Sector Clock mux to minimize the power consumption in a sector that has no clocks.

The clock can either come from the Column Clock or from the Plane 4 express bus. The extreme-right Column Clock mux has two additional multiplexed inputs as well, FCK3 and FCK4, to provide fast clocking to I/Os.

The register in each cell is triggered on a rising clock edge by default. Before configuration at power-up, constant “0” is provided to each register’s clock pins. After configuration at power-up, the registers either set or reset, depending on the user’s choice. The clocking scheme is designed to allow efficient use of multiple clocks with low clock skew, both within a column and across the core cell array.

Refer to **Registers** section about GCK and FCK activation or deactivation using IDS tools. All GCK and FCK lines are activated by default.

Figure 13-5. FPGA Clock repartition by column

**Figure 13-6. Column Clocking Overview**

### 13.2.1 Global Clock

Each of the eight dedicated Global Clock buses is connected to one of the dual-use Global Clock pins. Any clocks used in the design should use global clocks where possible. These signals are distributed across the top edge of the FPGA along special high-speed buses. Global Clock signals can be distributed throughout the overall FPGA with less than 1 ns skew.

This can be done by using Assign Pin Locks command in the IDS software to lock the clocks to the Global Clock locations.

### 13.2.2 Fast Clock

The fast clocks are used to provide fast clocking on the first/last stage of a structure close to the pad of the devices. They are only accessible on the far east/west area of the FPGA.

There are 2 Fast Clocks inputs (FCK3 FCK4) on the ATF697FF. Even the derived clocks can be routed through the Global network. Access points are provided in the corners of the array to route the derived clocks into the global clock network.

On the extreme east of the device, FCK3 and FCK4 inputs are internally multiplexed. This allows use of a fast clocking for the east-side I/Os. FCK3 and FCK4 are multiplexed: only one of these two FCKs can be used at a time.

The IDS software tools handle derived clocks to global clock connections automatically if used.

## 13.3 Reset System: reconfigurable unit part

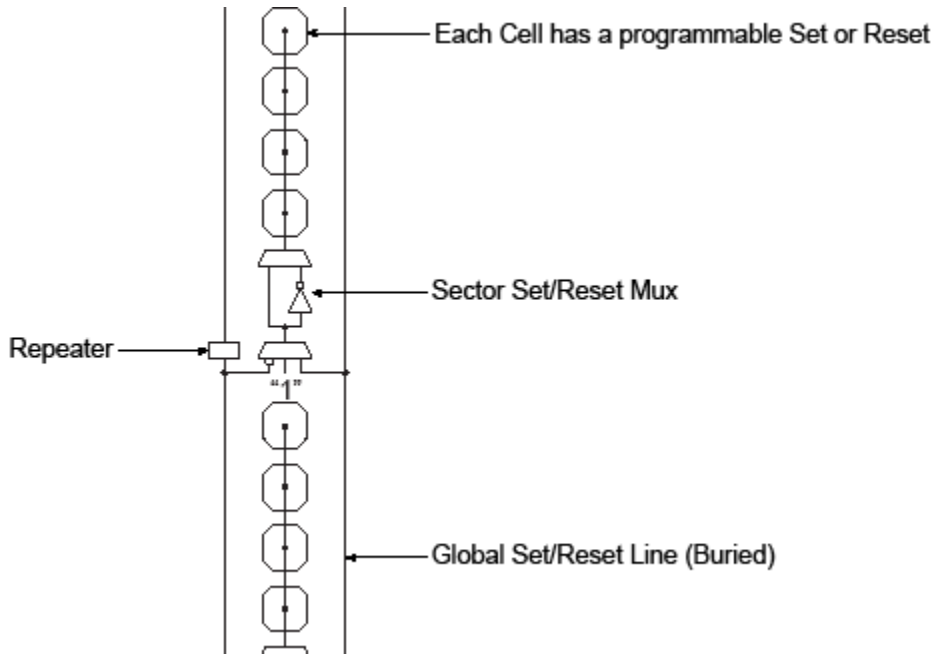

The ATF697FF reconfigurable unit reset scheme is essentially the same as the clock scheme except that there is only one differential Global Reset. A dedicated Global Set/Reset bus can be driven by any User I/O, except those used for clocking (Global Clocks or Fast Clocks). Like the clocking scheme, set/reset scheme is SET hardened.

The automatic placement tool will choose the reset net with the most connections to use the global resources. You can change this by using an RSBUF component in your design to indicate the global reset. Additional resets will use the express bus network.

The Global Set/Reset is distributed to each column of the array. Like Sector Clock mux, there is Sector Set/Reset mux at every four cells. Each sector column of four cells is set/reset by a Plane 5 express bus or Global Set/Reset using the Sector Set/Reset mux (Figure 10). The set/reset provided to each sector column of four cells is either inverted or non-inverted using the Sector Reset mux.

The function of the Set/Reset input of a register is determined by a configuration bit in each cell. The Set/Reset input of a register is active low (logic 0) by default. Setting or Resetting of a register is asynchronous. Before configuration on power-up, a logic 1 (a high) is provided by each register (i.e., all registers are set at power-up).

Figure 13-7. Set/Reset

## 14. Debug interface: DSU

**Caution:** This chapter is for information purpose only.

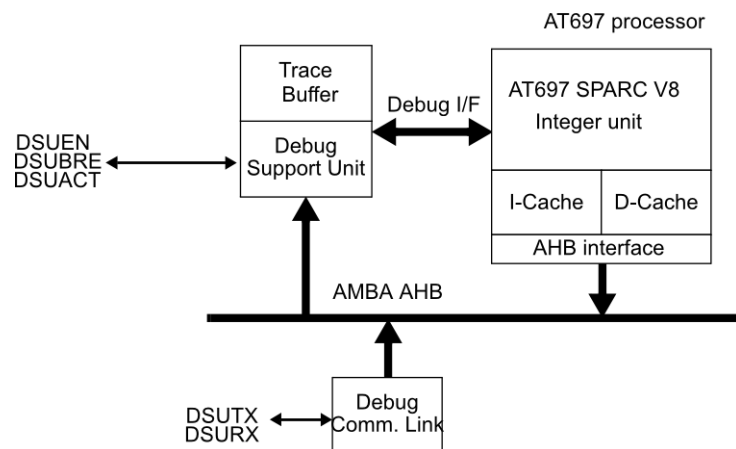

**Caution:** As its name clearly states, the Debug Support Unit is exclusively meant for debugging purpose. None of the DSU features shall ever be used in the final application where the DSU shall be turned into an inactive state (DSUEN, DSURX and DSUBRE tied to a permanent low level).

### 14.1 Overview

The ATF697FF processor includes a hardware debug support unit to aid in software debugging in the final application. The support is provided through two modules: a debug support unit (DSU) and a debug communication link (DCL).

The DSU can put the processor in debug mode, allowing read/write access to all processor registers and cache memories. The DSU also contains a trace buffer which stores executed instructions or data transfers on the internal bus. The debug communications link implements a simple read/write protocol and uses standard asynchronous UART communications.

**Figure 14-1. Debug Support Unit and Communication Link**

It is possible to debug the processor through any master on the internal bus. The PCI interface is build in as a master on the internal bus. All debug features are available from any PCI master.

### 14.2 Debug Support Unit

The debug support unit is used to control the trace buffer and the processor debug mode. The DSU master occupies a 2 MB address space on the internal bus. Through this address space, any other masters like PCI can access the processor registers and the contents of the trace buffer.

The DSU control registers can be accessed at any time, while the processor registers and caches can only be accessed when the processor has entered debug mode. The trace buffer can be accessed only when tracing is disabled or completed. In debug mode, the processor pipeline is held and the processor is controlled by the DSU.

Debug mode can only be entered when the debug support unit is enabled through an external pin (DSUEN). Driving the DSUEN pin high enables the debug support unit. Entering debug mode occurs on the following events (provided the appropriate setup was performed, see notes):

- executing a breakpoint instruction (ta 1)<sup>1</sup>

- integer unit hardware breakpoint/watchpoint hit (trap 0x0B)<sup>2</sup>
- rising edge of the external break signal (DSUBRE)<sup>2</sup>
- setting the break-now bit (DSUC.bn = 1)<sup>2</sup>
- a trap that would cause the processor to enter error mode<sup>3</sup>
- occurrence of any, or a selection of traps as defined in the DSU control register<sup>4</sup>
- after a single-step operation<sup>5</sup>
- DSU breakpoint hit<sup>6</sup>
- instead of entering Error Mode<sup>7</sup>

Note: 1. Only after the break-on-S/W-breakpoint was set (DSUC.bs = 1)

Note: 2. Only after the break-on-IU-watchpoint was set (DSUC.bw = 1)

Note: 3. Only after the break-on-error-traps was set (DSUC.bz = 1)

Note: 4. Only after the break-on-trap was set (DSUC.bx = 1)

Note: 5. Only after the single-step was set (DSUC.ss = 1)

Note: 6. Only after the break-on-DSU-breakpoint was set (DSUC.bd = 1)

Note: 7. Only after the break-on-error was set (DSUC.be = 1)

When debug mode is entered, the following actions are taken:

- PC and nPC are saved in temporary registers (accessible by the debug unit)
- an output signal (DSUACT) is asserted to indicate the debug state
- the timer unit is (optionally) stopped to freeze the ATF697FF processor timers and watchdog

The instruction that caused the processor to enter debug mode is not executed, and the processor state is kept unmodified. Execution is resumed by clearing the break-now bit (DSUC.bn = 0) or by de-asserting DSUEN. The timer unit will be re-enabled and execution will continue from the saved PC and nPC. Debug mode can also be entered after the processor has entered error mode, for instance when an application has terminated and halted the processor. The error mode can be cleared and the processor restarted at any address.

### 14.2.1 DSU Breakpoint

The DSU contains two breakpoint registers for matching either internal bus addresses or executed processor instructions. A breakpoint hit is typically used to freeze the trace buffer, but can also put the processor in debug mode.

Freeze operation can be delayed by programming the trace buffer delay counter (DSUC.dcnt) to a non-zero value. In this case, the trace buffer delay counter value (DSUC.dcnt) is decremented for each additional trace until it reaches zero, after which the trace buffer is frozen. If the break on trace freeze bit is set (DSUC.bt = 1), the DSU forces the processor into debug mode when the trace buffer is frozen.

Note: Due to pipeline delays, up to 4 additional instruction can be executed before the processor is placed in debug mode.

A mask register is associated with each breakpoint, allowing breaking on a block of addresses. Only address bits with the corresponding mask bit set to '1' are compared during breakpoint detection.

### 14.2.2 Time Tag

The DSU implements a time tag counter. The time tag counter is incremented each clock as long as the processor is running. The counter is stopped when the processor enters debug mode, and restarted when execution is resumed.

The time tag counter is stored in the trace as an execution time reference.

### 14.2.3 Trace Buffer

The trace buffer consists in a circular buffer that stores the executed instructions and/or the internal bus data transfers. The size of the trace buffer is 512 lines of 16 bytes. The trace buffer operation is controlled through the DSU control register (DSUC) and the trace buffer control register (TBCTL). When the processor enters debug mode, tracing is suspended.

The trace buffer can contain the executed instructions, the transfers on the internal bus or both (mixed-mode). The trace buffer control register (TBCTL) contains an instruction trace index counter (TBCTL.icnt) and an internal bus trace index counter (TBCTL.bcnt) that store the address of the trace buffer location that will be written on next trace. Since the buffer is circular, they actually point to the oldest entry in the buffer. The index counters are automatically incremented after each stored trace entry.

The trace buffer operation is controlled as follows:

- Tracing can be globally enabled/disabled (DSUC.te)
- Instruction tracing can be enabled/disabled (TBCTL.ti)
- Internal bus tracing can be enabled/disabled (TBCTL.ta)
- Internal bus trace freeze on entry into debug mode can be enabled/disabled (TBCTL.af)

#### 14.2.3.1 Instruction trace

When instruction tracing is enabled (TBCTL.ti = 1), one instruction is stored per line in the trace buffer with the exception of multi-cycle instructions. Multi-cycle instructions can be entered two or three times in the trace buffer:

- For store instructions, bits [95:64] correspond to the store address on the first entry and to the stored data on the second entry (and third in case of STD). Bit 126 is set logical one on the second and third entry to indicate this.
- A double load (LDD) is entered twice in the trace buffer, with bits [95:64] containing the loaded data.
- Multiply and divide instructions are entered twice, but only the last entry contains the result. Bit 126 is set for the second entry.
- For FPU operation producing a double-precision result, the first entry contains the most-significant 32 bits of the results in bits [63:32] while the second entry contains the least-significant 32 bits in bits [63:32].

**Table 14-1. Instruction Trace Buffer Line Allocation**

Bits	Name	Definition
127	Instruction breakpoint hit	Set to '1' if a DSU instruction breakpoint hit occurred.
126	Multi-cycle instruction	Set to '1' on the second and third instance of a multi-cycle instruction (LDD, ST or FPop)
125:96	Time tag counter	The value of the DSU time tag counter
95:64	Load/Store parameters	Instruction result, store address or store data
63:34	Program counter	Program counter (2 lsb bits removed since they are always zero)
33	Instruction trap	Set to '1' if traced instruction trapped
32	Processor error mode	Set to '1' if the traced instruction caused processor error mode
31:0	Opcode	Instruction opcode

Note: When a trace is frozen, a watchpoint\_detected trap (0x0B) is generated.

### 14.2.3.2 Bus Trace

When internal bus tracing is enabled (TBCTL.ta = 1), one internal bus operation is stored per line in the trace buffer.

**Table 14-2. Internal Bus Trace Buffer Line Allocation**

Bits	Name	Definition
127	AHB breakpoint hit	Set to '1' if a DSU AHB breakpoint hit occurred.
126	-	Unused
125:96	DSU counter	The value of the DSU counter
95:92	IRL	Processor interrupt request input
91:88	PIL	Processor interrupt level (PSR.pil)
87:80	Trap type	Processor trap type (PSR.tt)
79	Hwrite	AHB HWRITE*
78:77	Htrans	AHB HTRANS
76:74	Hsize	AHB HSIZE
73:71	Hburst	AHB HBURST
70:67	Hmaster	AHB HMASTER
66	Hmastlock	AHB HMASTLOCK
65:64	Hresp	AHB HRESP
63:32	Load/Store data	AHB HRDATA or HWDATA
31:0	Load/Store address	AHB HADDR

### 14.2.3.3 Mixed Trace

In mixed mode, the buffer is divided in two halves, with instructions stored in the lower half and bus transfers in the upper half. The most-significant bit of the internal bus trace index counter is then automatically kept high, while the most-significant bit of the instruction trace index counter is kept low.

### 14.2.4 DSU Memory Map

**Table 14-3. DSU Map**

Address	Register
0x90000000	DSU control register
0x90000004	Trace buffer control register
0x90000008	Time tag counter
0x90000010	AHB break address 1
0x90000014	AHB mask 1
0x90000018	AHB break address 2

0x9000001C	AHB mask 2
0x90010000 0x9001FFFC	Trace buffer
0x9001...0	Trace bits 127 96
0x9001...4	Trace bits 95 64
0x9001...8	Trace bits 63 32
0x9001...C	Trace bits 31 0
0x90020000 0x9003FFFC	IU/FPU register file
0x90080000 0x900FFFFC	IU special purpose registers
0x90080000	Y register
0x90080004	PSR register
0x90080008	WIM register
0x9008000C	TBR register
0x90080010	PC register
0x90080014	nPC register
0x90080018	FSR register
0x9008001C	DSU trap register
0x90080040	ASR16
0x90080060 0x9008007C	ASR24 ASR31
0x90100000 0x9013FFFC	Instruction cache tags
0x90140000 0x9017FFFC	Instruction cache data
0x90180000 0x901BFFFC	Data cache tags
0x901C0000 0x901FFFFC	Data cache data

The IU/FPU registers address depends on the number of register windows implemented. The registers are accessed at the following addresses (WINDOWS = total number of implemented SPARC register windows = 8,  $0 \leq \text{window} < \text{WINDOWS}$ ):

- %on:  $0x90020000 + (((\text{window} \times 64) + 32 + 4 \times n) \bmod (\text{WINDOWS} \times 64))$
- %ln:  $0x90020000 + (((\text{window} \times 64) + 64 + 4 \times n) \bmod (\text{WINDOWS} \times 64))$
- %in:  $0x90020000 + (((\text{window} \times 64) + 96 + 4 \times n) \bmod (\text{WINDOWS} \times 64))$
- %gn:  $0x90020000 + (\text{WINDOWS} \times 64) + 128 + 4 \times n$
- %fn:  $0x90020000 + (\text{WINDOWS} \times 64) + 4 \times n$

## 14.2.5 Debug Operations

### 14.2.5.1 Instruction Breakpoints

To insert instruction breakpoints, the breakpoint instruction (ta 1) should be used. This will leave the four IU hardware breakpoints free to be used as data watchpoints. Since cache snooping is only performed on the data cache, the instruction cache must be flushed after the insertion or removal of breakpoints. To minimize the influence on execution, it is enough to clear the corresponding instruction cache tag (which is accessible through the DSU).

The DSU hardware breakpoints should only be used to freeze the trace buffer, and not for software debugging since there is a 4-cycle delay from the breakpoint hit before the processor enters the debug mode.

### 14.2.5.2 Single Stepping

When single-stepping is enabled (TBCTL.ss = 1), clearing the break-now bit (TBCTL.bn = 0) resumes processor execution for one instruction and then automatically re-enters debug mode.

### 14.2.6 DSU Trap

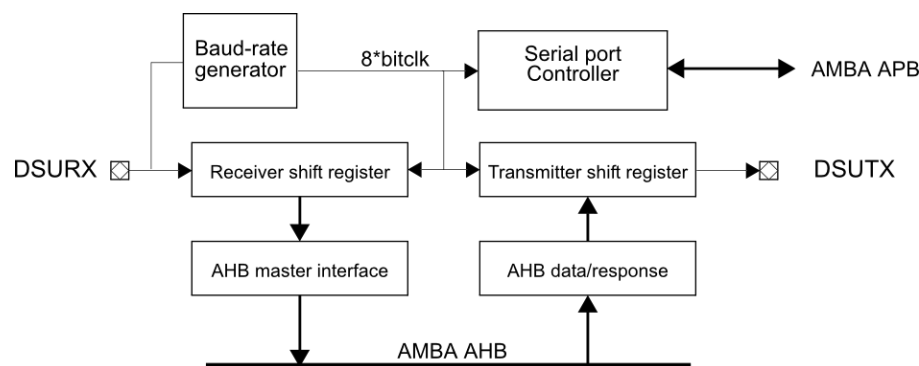

The DSU trap register (DTR) consists in a read-only register that indicates which SPARC trap type caused the processor to enter debug mode.

When debug mode is forced by asserting the break-now bit (TBCTL.bn = 1), a watchpoint\_detected trap (0x0B) is generated.

## 14.3 DSU Communication Link

DSU communication link consists of a UART connected to the internal bus as a master.

Figure 14-2. DSU Communication Link Block Diagram

A simple communication protocol is supported to transmit access parameters and data. A link command consists of a control byte, followed by a 32-bit address, followed by optional write data. If the DSU link response is enabled (DSUC.lr = 1), a response byte is sent after each read/write access. If disabled, a write access does not return any response, while a read access only returns the read data.

### 14.3.1 Data Frame

A DSU data frame consists in a start bit, 8 data bits and a stop bit..

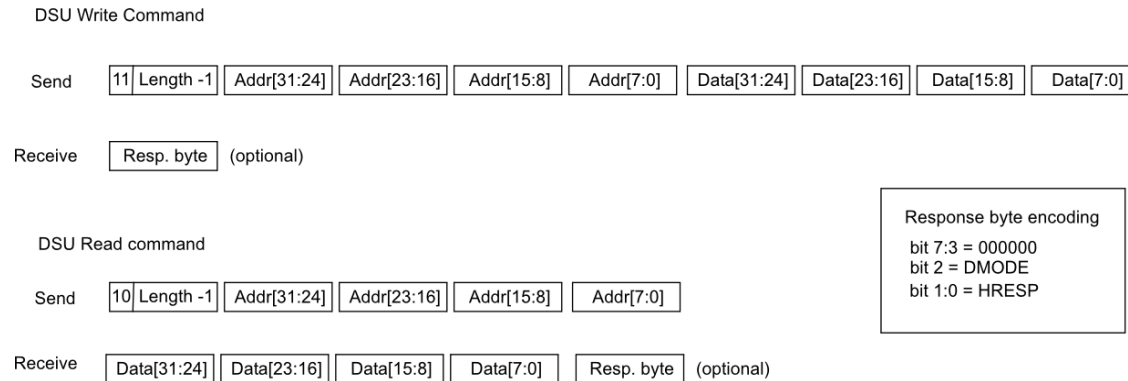

Figure 14-3. DSU UART Data Frame

### 14.3.2 Commands

Through the communication link, a read or write transfer can be generated to any address on the internal bus. A response byte is optionally sent when the processor goes from execution mode to debug mode. Block transfers can be performed by setting the length field to n-1, where n denotes the number of transferred words. For write accesses, the control byte and address is sent once, followed by the number of data words to be written. The address is automatically incremented after each data word. For read accesses, the control byte and address is sent once and the corresponding number of data words is returned.

**Figure 14-4. DSU Command**

### 14.3.3 Clock Generation

The UART contains an 16-bit down-counting scaler to generate the desired baud-rate. The scaler counter is clocked by the system clock and generates a UART tick each time it underflows. The counter is reloaded with the value of the UART scaler reload register (DSUUR.rv) after each underflow. The resulting UART tick frequency is 8 times the desired baud-rate.

If not programmed in software, the baud-rate is automatically discovered. This is done by searching for the shortest period between two falling edges of the received data (corresponding to two bit periods). When three identical two-bit periods has been found, the corresponding scaler reload value is latched into the reload register (DSUUR.rv), the baud-rate locked bit is set (DSUUC.bl = 1) and the UART is enabled (DSUUC.uen = 1). If the baud-rate locked bit is cleared in software (DSUUC.bl = 0), the baud-rate discovery process is restarted. The baud-rate discovery is also restarted when a break is detected on the serial line by the receiver, allowing to change the baud-rate from the external transmitter. For proper baud-rate detection, a break followed by the value 0x55 should be transmitted to the receiver.

The best scaler value for manually programming the baudrate can be calculated as follows:

$$scaler_{rv} = \frac{sdclk_{freq}}{baudrate \times 8} - 1$$

$$baudrate = \frac{sdclk_{freq}}{8 \times (scaler_{rv} + 1)}$$

## 14.4 Booting from DSU

By asserting DSUEN and DSUBRE at reset time, the processor will directly enter debug mode without executing any instructions. The system can then be initialized from the communication link, and applications can be downloaded and debugged. Additionally, external (flash) PROMs for standalone booting can be re-programmed.

## 14.5 JTAG

The processor part and the reconfigurable unit part embed the JTAG functionality. However, the JTAG functionality is not accessible on the ATF697FF due to the product implementation.

**Caution:** In order to completely deactivate the JTAG functionality for the final application, the following steps shall be performed:

- The pin 94 shall be connected to VSS.
- The pin 131 shall be connected to VSS.
- The pin 133 shall be connected to VSS.
- The pin 134 shall be connected to VSS.
- In the configuration register of the reconfigurable unit, the CR5 bit field shall be set at '1'.

## 15. Register Description

**Table 15-1. Register Legend**

**Address:** 0x01010101

Bit Number	31	30	29	28	27	26	25	24	23	...	...	...	...	9	8	7	6	5	4	3	2	1	0
field name	field				reserved										bit								
access type	r = read-only					w = write-only										r/w = read & write							
default value after reset	0	100		1		x = undefined or non affected by reset										p = depends on the value of one or more external pins							

Note: All registers are equally accessible in user and supervisor mode.

Note: Reserved fields usually are read-only (unless specified otherwise) and writing them usually has no side effects (unless specified otherwise) but should better be done with their default value for compatibility with possible use of the field in future revisions of the product.

Note: Writing to read-only fields or registers has no effect.

## 15.1 Integer Unit Registers

Table 15-2. Processor State Register PSR

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
impl				ver				icc				reserved				ec	ef	pil				s	ps	et	cwp						
								n	z	v	c							r	r												
r				r				r/w				r				r	r	r/w				r/w			r	r/w					
0000				0000				x	x	x	x	0000 00				x	x	xxxx				1	x	0	00		xxx				

Bit Number	Mnemonic	Description
31..28	impl	Implementation Implementation or class of implementations of the architecture.
27..24	ver	Version Identify one or more particular implementations or is a readable and writable state field whose properties are implementation-dependent.
23	n	Negative Indicates whether the 32-bit 2's complement ALU result was negative for the last instruction that modified the icc field (1 = negative, 0 = not negative).
22	z	Zero Indicates whether the 32-bit ALU result was zero for the last instruction that modified the icc field (1 = zero, 0 = nonzero).
21	v	Overflow Indicates whether the ALU result was within the range of (was representable in) 32-bit 2's complement notation for the last instruction that modified the icc field (1 = overflow, 0 = no overflow)
20	c	Carry Indicates whether a 2's complement carry out (or borrow) occurred for the last instruction that modified the icc field. Carry is set on addition if there is a carry out of bit 31: Carry is set on subtraction if there is borrow into bit 31 (1 = carry/borrow, 0 = no carry/borrow).
13	ec	Enable Coprocessor Determines whether the implementation-dependent coprocessor is enabled (1 = enabled, 0 = disabled). If disabled, a coprocessor instruction will trap. Although this bit is marked as read/write, this implementation has no coprocessor and will always behave as the coprocessor is permanently disabled.
12	ef	Enable Floating-Point Determines whether the FPU is enabled (1 = enabled, 0 = disabled). If disabled, a floating-point instruction will trap.

Bit Number	Mnemonic	Description
11..8	pil	Processor Interrupt Level Identify the interrupt level above which the processor will accept an interrupt. Interrupt 15 is not maskable (NMI) in the IU and is always accepted whatever the current processor interrupt level (however, interrupt masking is still possible in ITMP).
7	s	Supervisor Determines whether the processor is in supervisor or user mode (1 = supervisor mode, 0 = user mode).
6	ps	Previous Supervisor Contains the value of the s bit at the time of the most recent trap.
5	et	Enable Traps Determines whether traps are enabled (1 = traps enabled, 0 = traps disabled). A trap automatically resets it to 0. When 0, an interrupt request is ignored and an exception trap causes the IU to halt execution and enter error-mode.
4..0	cwp	Current Window Pointer A counter that identifies the current window into the r registers. The hardware decrements cwp on traps & SAVE instructions and increments it on RESTORE & RETT instructions (modulo 8).

Note: This TMR-protected register can be safely read after power-up without prior initialization. However, bits unaffected by the reset operation will have an undetermined value.

Note: This register is read and written using the privileged RDPSR and WRPSR instructions.

**Table 15-3. Window Invalid Mask Register WIM**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
reserved																							w7	w6	w5	w4	w3	w2	w1	w0	
r																							r/w								
0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	x	x	x	x	x	x	x	x

Bit Number	Mnemonic	Description
0 < n < 7	wn	Window n Invalid Mask Determines whether a window overflow or underflow trap is to be generated on an invalid-marked window by a SAVE, RESTORE, or RETT instruction (1 = invalid, 0 = valid).

Note: This TMR-protected register can be safely read after power-up without prior initialization. However, bits unaffected by the reset operation will have an undetermined value.

Note: This register is read and written using the privileged RDWIM and WRWIM instructions.

**Table 15-4. Multiply/Divide Register Y**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
y																															
r/w																															
xxxx xxxx xxxx xxxx xxxx xxxx xxxx xxxx																															

Bit Number	Mnemonic	Description
31..0	y	<p>Y Register</p> <p>Contains the most significant word of the double-precision product of an integer multiplication, as a result of either an integer multiply instruction (SMUL, SMULcc, UMUL, UMULcc), or of a routine that uses the integer multiply step instruction (MULScC). Also holds the most significant word of the double-precision dividend for an integer divide instruction (SDIV, SDIVcc, UDIV, UDIVcc).</p>

Note: This TMR-protected register can be safely read after power-up without prior initialization. However, bits unaffected by the reset operation will have an undertermined value.

Note: This register is read and written using the non-priviledged RDY and WRV instructions.

**Table 15-5. Trap Base Register TBR**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
tba												tt						reserved													
r/w												r						r													
xxxx xxxx xxxx xxxx xxxx												xxxx xxxx						0000													

Bit Number	Mnemonic	Description
31..12	tba	<p>Trap Base Address</p> <p>The most-significant 20 bits of the trap table address.</p>
11..4	tt	<p>Trap Type</p> <p>Written by the hardware when a trap occurs (except for an external reset request), and retains its value until the next trap. It provides an offset into the trap table.</p>

Note: This TMR-protected register can be safely read after power-up without prior initialization. However, bits unaffected by the reset operation will have an undetermined value.

Note: This register is read and written using the priviledged RDTBR and WRTBR instructions.

**Table 15-6. Program Counter PC**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
pc																															
0x00000000																															

Bit Number	Mnemonic	Description
31..0	pc	Program Counter Contains the address of the instruction currently being executed by the IU. When a trap occurs, it is saved into a local register (I1). When returning from the trap, the local register is copied back.

**Table 15-7. Next Program Counters nPC**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
npc																															
0x00000004																															

Bit Number	Mnemonic	Description
31..0	npc	Next Program Counter Holds the address of the next instruction to be executed by the IU (assuming a trap does not occur). When a trap occurs, it is saved into a local register (I2). When returning from the trap, the local register is copied back.

**Table 15-8. Watch Point Address Registers ASR24, ASR26, ASR28 and ASR30**

**Address:** %asr24, %asr26, %asr28, %asr30

waddr																														reserve	r	i
r/w																														r	r	f
xxxx xxxx xxxx xxxx xxxx xxxx xxxx xx																														0	0	0

Bit Number	Mnemonic	Description
31..2	waddr	Watchpoint Address Defines the address range to be watched.
0	if	Hit on Instruction Fetch If set, enables hit generation on instruction fetch.

Note: These TMR-protected registers can be safely read after power-up without prior initialization. However, bits unaffected by the reset operation will have an undetermined value.

Note: These non-privileged registers are read and written using the RDASR and WRASR instructions.

**Table 15-9. Watch Point Mask Registers ASR25, ASR27, ASR29 and ASR31**

**Address:** %asr25, %asr27, %asr29, %asr31

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
wmask																dl	ds														
r/w																r	r														
																w	w														
xxxx xxxx xxxx xxxx xxxx xxxx xxxx xx																0	0														

Bit Number	Mnemonic	Description
31..2	wmask	Watchpoint Address Mask Defines which bits are to be compared to the matching watchpoint address (0 = comparison disabled, 1 = comparison enabled).
1	dl	Hit on Data Load If set, enables hit generation on data load.
0	ds	Hit on Data Store If set, enables hit generation on data store.

Note: These TMR-protected registers can be safely read after power-up without prior initialization. However, bits unaffected by the reset operation will have an undetermined value.

Note: These non-privileged registers are read and written using the RDASR and WRASR instructions.

**Table 15-10. Register File Protection Control Register ASR16**

**Address:** %asr16

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
reserved											cnt			tcb						te		di									
r											r/w			r/w						r / w		r / w									
XXXX XXXX XXXX XXXX XXXX											xxx			x XXXX XX						0		0									
Bit Number	Mnemonic	Description																													
11..9	cnt	Error Counter. Incremented each time a register correction is performed (but saturates at 111).																													
8..2	tcb	Test Checkbits If the test mode is enabled, the destination register checksum is XORed with this field before being written to the register file.																													
1	te	Test Enable If set, errors can be inserted in the register file to test the EDAC protection function.																													
0	di	Disable Checking If set, disables the register-file checking function.																													

Note: This TMR-protected register can be safely read after power-up without prior initialization. However, bits unaffected by the reset operation will have an undetermined value.

Note: This non-privileged register is read and written using the RDASR and WRASR instructions.

## 15.2 Floating-Point Unit Registers

Table 15-13. FPU Status Register FSR

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0		
rd	reserved			tem					ns	reserved		ver		ftt		reserved		fcc						aexc					cexc				
				nvm	ofm	ufm	dzm	nxm															nva	ofa	ufa	dza	nxa	nvc	ofc	ufc	dzc	nxc	
r/w	r			r/w					r	r		r		r		r		r						r/w					r/w				
xx	00			x	x	x	x	x		0	00		000		xxx		00		xx				x	x	x	x	x	x	x	x	x	x	

Bit Number	Mnemonic	Description
31..30	rd	Rounding Direction Selects the rounding direction for floating-point results according to ANSI/IEEE Standard 754-1985 (00 = to nearest, 01 = to zero, 10 = to +∞, 11 = to -∞).
27..23	tem	Trap Enable Mask Enable bits for each of the five floating-point exceptions that can be indicated in the current_exception field (cexc). If a floating-point operate instruction generates one or more exceptions and the corresponding mask bit is 1, an fp_exception trap is caused. A value of 0 prevents that exception type from generating a trap.
22	ns	Non Standard Floating-Point Not implemented, always reads as 0.
19..17	ver	FPU Version Number
16..14	ftt	Floating-Point Trap Type After a floating-point exception occurs, this field encodes the type of floating-point exception until an STFSR or another FPop is executed.
11..10	fcc	Floating-Point Condition Codes Updated by the floating-point compare instructions (FCMP and FCMPE). The floating-point conditional branch instruction (FBfcc) bases its control transfer on this field.
9..5	aexc	Accrued Floating-Point Exceptions Accumulate IEEE-754 floating-point exceptions while fp_exception traps are disabled using the tem field. After an FPop completes, the tem and cexc fields are logically ANDed together. If the result is nonzero, an fp_exception trap is generated; otherwise, the new cexc field is ORed into this field. Thus, while traps are masked, exceptions are accumulated in this field.

Bit Number	Mnemonic	Description
4..0	cexc	Current Floating-Point Exceptions Indicate that one or more IEEE-754 floating-point exceptions were generated by the most recently executed FPop instruction. The absence of an exception causes the corresponding bit to be cleared.

Note: This TMR-protected register can be safely read after power-up without prior initialization. However, bits unaffected by the reset operation will have an undetermined value.

Note: This register is read and written using the non-privileged LDFSR and STFSR instructions.

**Table 15-14. Floating-Point Trap Types ftt**

**Trap Type Definition**

ftt	Name	Description
0	none	No trap.
1	IEEE_754_exception	An IEEE_754_exception floating-point trap type indicates that a floating-point exception occurred that conforms to the ANSI/IEEE Standard 754-1985. The exception type is encoded in the cexc field.
2	reserved	reserved
3	reserved	reserved
4	sequence_error	A sequence_error indicates one of three abnormal error conditions in the FPU, all caused by erroneous supervisor software: An attempt was made to execute a floating-point instruction when the FPU was not able to accept one. This type of sequence_error arises from a logic error in supervisor software that has caused a previous floating-point trap to be incompletely serviced (for example, the floating-point queue was not emptied after a previous floating-point exception). An attempt was made to execute a STDFQ instruction when the floating-point deferred-trap queue (FQ) was empty, that is, when FSR.qne = 0. (Note that generation of sequence_error is recommended, but not required in this case)
5	reserved	reserved
6	reserved	reserved
7	reserved	reserved

**Table 15-15. Floating-Point Condition Code fcc**

**fcc Field Definition**

fcc	Description
0	frs1 = frs2
1	frs1 < frs2

fcc	Description
2	frs1 > frs2
3	frs1 ? frs2 Indicates an unordered relation, which is true if either frs1 or frs2 is a signaling NaN or quiet NaN

Note: frs1 and frs2 correspond to the single, double, or quad values in the f registers specified by an instruction's rs1 and rs2 fields. Note that fcc is unchanged if FCMP or FCMPE generate an IEEE\_754\_exception trap.

**Table 15-16. Floating-Point Exception Fields aexc / cexc**

The accrued and current exception fields and the trap enable mask assume the following definitions of the floating-point exception conditions.

**Table 15-17. Exception Fields**

Aexc Mnemonic	Cexc Mnemonic	Name	Description
nva	nvc	Invalid	An operand is improper for the operation to be performed (1 = invalid operand, 0 = valid operand(s)). Examples: $0 \div 0$ , $\infty \infty$ are invalid.
ofa	ofc	Overflow	The rounded result would be larger in magnitude than the largest normalized number in the specified format (1 = overflow, 0 = no overflow).
ufa	ufc	Underflow	The rounded result is inexact and would be smaller in magnitude than the smallest normalized number in the indicated format (1 = underflow, 0 = no underflow). Underflow is never indicated when the correct unrounded result is zero. if $ufm = 0$ : The ufc and ufa bits will be set if the correct unrounded result of an operation is less in magnitude than the smallest normalized number and the correctly-rounded result is inexact. These bits will be set if the correct unrounded result is less than the smallest normalized number, but the correct rounded result is the smallest normalized number. nxc and nxa are always set as well. if $ufm = 1$ : An IEEE_754_exception trap will occur if the correct unrounded result of an operation would be smaller than the smallest normalized number. A trap will occur if the correct unrounded result would be smaller than the smallest normalized number, but the correct rounded result would be the smallest normalized number.
dza	dzc	Div_by_zero	$X \div 0$ , where X is subnormal or normalized. Note that $0 \div 0$ does not set the dzc bit. 1 = division-by-zero, 0 = no division-by-zero.
nxa	nxc	Inexact	The rounded result of an operation differs from the infinitely precise correct result. 1 = inexact result, 0 = exact result.

**Table 15-18. Floating-point Registers fn (0 < n < 31)**

fn																															
r/w(caution)																															
XXXX XXXX XXXX XXXX XXXX XXXX XXXX XXXX																															

**Caution:** These EDAC-protected registers come uninitialized after power-up so each register shall be first initialized before it can be safely read. Reading an uninitialized register may trigger a single-bit or a double-bit error in an undeterministic manner.

### 15.3 Memory Interface Registers

**Table 15-19. Memory Configuration Register 1 MCFG1**

**Address:** 0x80000000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
reserved	pbrdy	abrdy	iowdh	iobrdy	bexc	reserved			iows		ioen					reserved				prwen	reserved	prwdh				prwvs					prrws
r	r / w	r / w	r/w	r / w	r / w	r			r/w		r / w					r				r / w	r	r/w				r/w				r/w	
0	0	0	xx	0	0	0			xxxx		0					000 0000				0	0	pp				1111				1111	

Bit Number	Mnemonic	Description
30	pbrdy	PROM area bus-ready enable. If set, a PROM access will be extended until BRDY* is asserted.
29	abrdy	Asynchronous bus ready If set, the BRDY* input can be asserted asynchronously to the system clock, provided it is at least 1.5 clock cycles long. Termination of the access after assertion of BRDY* will be delayed by at least one clock cycle.
28..27	iowdh	I/O bus width Defines the bus width of the I/O area (00 = 8, 10 = 32).
26	iobrdy	IO area bus ready enable If set, an IO access will be extended until BRDY* is asserted
25	bexc	Bus error enable for RAM, PROM and IO access If set, the assertion of the BEXC* will generate an error response on the internal bus and causes a trap (0x01, 0x09, 0x2B) depending on the access type.

Bit Number	Mnemonic	Description
23..20	iows	I/O waitstates Defines the number of waitstates during I/O accesses (0000 = 0, 0001 = 1, 0010 = 2,..., 1111 = 15).
19	ioen	I/O area enable 0 = read and write access to I/O area is disabled 1 = read and write access to I/O area is enabled.
11	prwen	PROM write enable If set, enables write cycles to the PROM area.
9..8	prwdh	PROM width Defines the bus width of the PROM area (00 = 8, 1X = 32). During reset, the PROM width is set with the value read on GPIO[1:0].
7..4	prwws	PROM write waitstates Defines the number of waitstates during PROM write cycles (0000 = 0, 0001 = 2,... 1111 = 30). During reset, the PROM write waitstates is set to the maximum to allow booting.
3..0	prrws	PROM read waitstates Defines the number of waitstates during PROM read cycles (0000 = 0, 0001 = 2,... 1111 = 30). During reset, the PROM read waitstates is set to the maximum to allow booting.

Note: In 8-bit PROM mode, the last 20% of each PROM bank are used to store the EDAC checksums when EDAC is enabled and cannot be used to store instructions or data.

**Table 15-20. Memory Configuration Register 2 MCFG2**

**Address:** 0x80000004

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

w	w	w		w		w		w		w		w				w	w	w			w	w	w	w	w	w						
0	1	111		1		000		10		00		0000				0	0	xxxx			0	x	x	xx	xx	xx						

Bit Number	Mnemonic	Description
31	sdrref	SDRAM refresh If set, the SDRAM refresh is enabled.
30	trp	SDRAM tRP timing tRP is equal to 2 or 3 system clocks (0 or 1).
29..27	trfc	SDRAM tRFC timing tRFC is equal to 3 + field-value system clocks.
26	sdrCAS	SDRAM CAS delay Selects 2 or 3 cycle CAS delay (0 or 1). When changed, a LOAD-COMMAND-REGISTER command must be issued at the same time. Also sets RAS/CAS delay (trCD).
25..23	sdrbs	SDRAM banks size Defines the banks size for SDRAM chip selects: 000 = 4 MB, 001 = 8 MB, 010 = 16 MB .... 111 = 512 MB.
22..21	sdrcls	SDRAM column size 00 = 256, 01 = 512, 10 = 1024, 11 = 4096 when sdrbs = 111, 2048 otherwise
20..19	sdrCmd	SDRAM command Writing a non-zero value generates an SDRAM command: 01 = PRECHARGE, 10 = AUTO-REFRESH, 11 = LOAD-COMMAND-REGISTER. The field is reset after command has been executed.
14	se	SDRAM enable If set, the SDRAM controller is enabled.
13	si	SRAM disable If set together with se (SDRAM enable), the static ram access is disabled.
12..9	rambs	SRAM bank size Defines the size of each ram bank (0000 = 8 KB, 0001 = 16 KB... 1111 = 256 MB).
7	rambrdy	SRAM area bus ready enable If set to 1, a RAM access to RAM bank 4 (RAMS* [4]) is extended until BRDY* is asserted.
6	rammw	Read-modify-write on the SRAM Enables read-modify-write cycles on sub-word writes to areas with common write strobe and/or EDAC protection.
5..4	ramwdh	SRAM bus width Defines the bus width of the SRAM area (00 = 8, 1X = 32).

Bit Number	Mnemonic	Description
3..2	ramwws	SRAM write waitstates Defines the number of waitstates during SRAM write cycles (00 = 0, 01 = 1, 10 = 2, 11 = 3).
1..0	ramrws	SRAM read waitstates Defines the number of waitstates during SRAM read cycles (00 = 0, 01 = 1, 10 = 2, 11 = 3).

**Table 15-21. Memory Configuration Register 3 MCFG3**

**Address:** 0x80000008

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

r	r	r	r/w											r	r	r	r	r/w													
11	00	1	xxx xxxx xxxx xxxx											0	0	x	p	xxxx xxxx													

Bit Number	Mnemonic	Description
31:30	rfc	Register file check bits Indicates how many checkbits are used for the register file (11 = 7 bits)
27	me	Memory EDAC Indicates if a memory EDAC is present
26..12	srcrv	SDRAM refresh counter reload value The period between each AUTO-REFRESH command is calculated as follows: $t_{REFRESH} = ((\text{reload value}) + 1) \div \text{SDCLKfrequency}$ .
11	wb	EDAC diagnostic write bypass When set, replace the EDAC checkbits with tcb on a store operation.
10	rb	EDAC diagnostic read When set, update tcb with the EDAC checkbits on instruction fetch or data load operation.

Bit Number	Mnemonic	Description
9	re	RAM EDAC enable When set, enables EDAC protection on the RAM area: SRAM read-modify-write on sub-word operation shall be enabled as well (MCFG2.rammw = 1) in order to maintain EDAC protection integrity SDRAM read-modify-write on sub-word operations is simultaneously activated with EDAC on RAM Memory shall be initialized before EDAC activation.
8	pe	PROM EDAC enable When set, enables EDAC protection on the PROM area. During reset, this bit is initialized with the value of GPIO[2].
7..0	tcb	Test checkbits This field replaces the normal checkbits during store operations when wb is set. It is also loaded with the memory checkbits during instruction fetch and data load operations when rb is set.

hea																															
$r^1/w^2$																															
xxxx xxxx xxxx xxxx xxxx xxxx xxxx xxxx																															

Bit Number	Mnemonic	Description
31:0	hea	Hardware Error Address Identifies the address of the failed access.

Note: 1. Read value is only valid when a hardware error was detected (FAILSR.hed = 1) and is not relevant otherwise (unpredictable value).

Note: 2. Written value is always discarded when no hardware error is detected (FAILSR.hed = 0).

**Table 15-30. Fail Status Register – FAILSR**

**Address:** 0x80000010

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0					
reserved																						eed	hed	het	hem			hes								
r																						r <sub>1</sub> / w <sub>2</sub>	r / w <sub>2</sub>	r <sup>3</sup> /w <sup>4</sup>												
0000 0000 0000 0000 0000 00																						x	0	x	xxxx			xxx								

Bit Number	Mnemonic	Description
9	eed	EDAC-correctable Error Detected Set when an EDAC-correctable memory error is detected <sup>1</sup> (register-file EDAC errors are handled separately). This bit is never cleared in hardware and shall be cleared in software so a new error can be registered <sup>2</sup> . This bit shall also be cleared before the EDAC is activated.
8	hed	Hardware Error Detected Set when a hardware error is detected (bus exception, write protection error, EDAC correctable and uncorrectable external memory error, PCI initiator error or PCI target error). This bit is never cleared in hardware and shall be cleared in software so a new hardware error can be registered and the hardware error-related fields updated <sup>2</sup> .
7	het	Hardware Error Type <sup>3</sup> Identifies the type of the failed access (0 = write, 1 = read).
6..3	hem	Hardware Error Module <sup>3</sup> Identifies the module impacted by the failed access (0000 = IU/FPU, 0001 = PCI Initiator, 0010 = PCI Target, 0011 = DSU Communication Module).
2..0	hes	Hardware Error Size <sup>3</sup> Identifies the size of the failed access (000 = byte, 001 = half-word, 010 = word, 011 = double-word).

Note: 1. Bit might be updated even when a hardware error was already detected (FAILSR.hed = 1).

Note: 2. These bits shall be cleared as soon as possible after the error was detected so no subsequent hardware error is missed after the initial detection. Moreover, the register read-and-clear operation shall be best performed by mean of a SWAP instruction so to minimize even further the time from read to clear.

Note: 3. Read value is only valid when a hardware error was detected (FAILSR.hed = 1) and is not relevant otherwise (unpredictable value).

Note: 4. Written value is always discarded while no hardware error is detected (FAILSR.hed = 0).

## 15.5 Caches Register

Table 15-31. Cache Control Register – CCR

Address: 0x80000014

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

r		r		r		r		r / w	w	w	r		r/w		r / w	r	r	r/w		r/w		r/w		r/w		r / w	r / w	r/w		r/w	
11		11		11		01		0	0	0	10		xx		0	0	0	xx		xx		xx		xx		x	x	00		00	

Bit Number	Mnemonic	Description
31..30	drepl	Data cache replacement policy 11 = Least Recently Used (LRU)
29..28	irepl	Instruction cache replacement policy 11 = Least Recently Used (LRU)
27..26	isets	Instruction cache associativity Number of ways in the instruction cache. 11 = 4 way associative
25..24	dsets	Data cache associativity Number of ways in the data cache. 01 = 2 way associative
23	ds	Data cache snoop enable If set, will enable data cache snooping.
22	fd	Flush data cache If set, will flush the data cache. Always reads as zero.
21	fi	Flush Instruction cache If set, will flush the instruction cache. Always reads as zero.
20..19	cpc	Cache parity bits Indicates how many parity bits are used to protect the caches. 10 = 2 parity bits
18..17	cptb	Cache parity test bits These bits are XOR'ed to the data and tag parity bits during diagnostic writes.
16	ib	Instruction burst fetch This bit enables burst fill during instruction fetch.

Bit Number	Mnemonic	Description
15	ip	Instruction cache flush pending This bit is set while an instruction cache flush operation is in progress.
14	dp	Data cache flush pending This bit is set while a data cache flush operation is in progress.
13..12	ite	Instruction cache tag error counter This field is incremented <sup>1</sup> every time an instruction cache tag parity error is detected.
11..10	ide	Instruction cache data error counter This field is incremented <sup>1</sup> each time an instruction cache data sub-block parity error is detected.
9..8	dte	Data cache tag error counter This field is incremented <sup>1</sup> every time a data cache tag parity error is detected.
7..6	dde	Data cache data error counter This field is incremented <sup>1</sup> each time an instruction cache data sub-block parity error is detected
5	df	Data Cache Freeze on Interrupt If set, the data cache will automatically be frozen when an asynchronous interrupt is taken.
4	if	Instruction Cache Freeze on Interrupt If set, the instruction cache will automatically be frozen when an asynchronous interrupt is taken.
3..2	dcs	Data Cache State X0 = disabled 01 = frozen 11 = enabled
1..0	ics	Instruction Cache State X0 = disabled 01 = frozen 11 = enabled.

Note: 1. The counter saturates at 11 (3 events) and shall be cleared in software so new events can later be registered.

## 15.6 Idle Register

Table 15-32. Idle Register – IDLE

Address: 0x80000018

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0	
																idle																
																w																
																n/a																

Bit Number	Mnemonic	Description
31..0	idle	A write to this register followed by a load access will cause the system to enter idle mode. This a write-only register (written value is not relevant), the value returned by a read is not relevant.

## 15.7 Timer Registers

**Table 15-33. Timer 1 Counter Register TIMC1**

Bit Number	Mnemonic	Description
15..0	iclear	Interrupt Clear If written with a 1, clears the corresponding bit(s) in the interrupt pending register. The value returned by a read is not relevant, this is a write-only register.

## 15.10 General Purpose Interface Registers

**Table 15-56. I/O Port Data Register – IODAT**

**Address:** 0x800000A0

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
meddat								lowdat								piodat															
r/w								r/w								r/w															
xxxx xxxx								xxxx xxxx								xxxx xxxx xxxx xxxx															

Bit Number	Mnemonic	Description
31..24	meddat <sup>1</sup>	D[15:8] bus value
23..16	lowdat <sup>1</sup>	D[7:8] bus value
15..0	piodat	GPIO[15:0] port value

Note: 1. These bits are only accessible as I/O ports when all areas (ROM, RAM and I/O) of the memory bus are in 8-bit mode (see “8-bit PROM and SRAM access”) and the SDRAM controller is not enabled.

**Table 15-57. I/O Port Direction Register – IODIR**

**Address:** 0x800000A4

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
reserved														meddir	lowdir	piodir[15:0]															
r														r	r	r/w															
0000 0000 0000 00														0	0	0000 0000 0000 0000															

Bit Number	Mnemonic	Description
17	meddir <sup>1</sup>	D[15:8] port direction (see note). 1 = output 0 = input
16	lowdir <sup>1</sup>	D[7:0] port direction (see note). 1 = output 0 = input

Bit Number	Mnemonic	Description
15..0	piodir	GPIO[15:0] port direction 1 = output 0 = input

Note: These bits are only accessible as I/O ports when all areas (ROM, RAM and I/O) of the memory bus are in 8-bit mode (see “8-bit PROM and SRAM access”) and the SDRAM controller is not enabled.

**Table 15-58. I/O Port Interrupt Register IOIT1**

**Address:** 0x800000A8

0	x	x	x xxxx					0	x	x	x xxxx					0	x	x	x xxxx					0	x	x	x xxxx				

Bit Number	Mnemonic	Description
31	en3	Enable. If set, the corresponding interrupt will be enabled, otherwise it will be masked.
30	le3	Level/edge triggered. If set, the interrupt will be edge-triggered, otherwise level sensitive.
29	pl3	Polarity If set, the corresponding interrupt will be active high (or edge-triggered on positive edge). Otherwise, it will be active low (or edge-triggered on negative edge).
28..24	isel3	I/O port select. The value of this field defines which I/O port (0 31) should generate parallel I/O port interrupt 3.
23	en2	Enable. If set, the corresponding interrupt will be enabled, otherwise it will be masked.
22	le2	Level/edge triggered. If set, the interrupt will be edge-triggered, otherwise level sensitive.
21	pl2	Polarity If set, the corresponding interrupt will be active high (or edge-triggered on positive edge). Otherwise, it will be active low (or edge-triggered on negative edge).
20..16	isel2	I/O port select. The value of this field defines which I/O port (0 31) should generate parallel I/O port interrupt 2.

Bit Number	Mnemonic	Description
15	en1	Enable. If set, the corresponding interrupt will be enabled, otherwise it will be masked.
14	le1	Level/edge triggered. If set, the interrupt will be edge-triggered, otherwise level sensitive.
13	pl1	Polarity If set, the corresponding interrupt will be active high (or edge-triggered on positive edge). Otherwise, it will be active low (or edge-triggered on negative edge).
12..8	isel1	I/O port select. The value of this field defines which I/O port (0 31) should generate parallel I/O port interrupt <sup>1</sup> .
7	en0	Enable. If set, the corresponding interrupt will be enabled, otherwise it will be masked.
6	le0	Level/edge triggered. If set, the interrupt will be edge-triggered, otherwise level sensitive.
5	pl0	Polarity If set, the corresponding interrupt will be active high (or edge-triggered on positive edge). Otherwise, it will be active low (or edge-triggered on negative edge).
4..0	isel0	I/O port select. The value of this field defines which I/O port (0 31) should generate parallel I/O port interrupt 0.

**Table 15-59. I/O Port Interrupt Register IOIT2**

**Address:** 0x800000AC

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

0	x	x	x xxxx			0	x	x	x xxxx			0	x	x	x xxxx			0	x	x	x xxxx										

Bit Number	Mnemonic	Description
31	en7	Enable. If set, the corresponding interrupt will be enabled, otherwise it will be masked.
30	le7	Level/edge triggered. If set, the interrupt will be edge-triggered, otherwise level sensitive.

Bit Number	Mnemonic	Description
29	pl7	Polarity If set, the corresponding interrupt will be active high (or edge-triggered on positive edge). Otherwise, it will be active low (or edge-triggered on negative edge).
28..24	isel7	I/O port select. The value of this field defines which I/O port (0 31) should generate parallel I/O port interrupt 7.
23	en6	Enable. If set, the corresponding interrupt will be enabled, otherwise it will be masked.
22	le6	Level/edge triggered. If set, the interrupt will be edge-triggered, otherwise level sensitive.
21	pl6	Polarity If set, the corresponding interrupt will be active high (or edge-triggered on positive edge). Otherwise, it will be active low (or edge-triggered on negative edge).
20..16	isel6	I/O port select. The value of this field defines which I/O port (0 31) should generate parallel I/O port interrupt 6.
15	en5	Enable. If set, the corresponding interrupt will be enabled, otherwise it will be masked.
14	le5	Level/edge triggered. If set, the interrupt will be edge-triggered, otherwise level sensitive.
13	pl5	Polarity If set, the corresponding interrupt will be active high (or edge-triggered on positive edge). Otherwise, it will be active low (or edge-triggered on negative edge).
12..8	isel5	I/O port select. The value of this field defines which I/O port (0 31) should generate parallel I/O port interrupt 5.
7	en4	Enable. If set, the corresponding interrupt will be enabled, otherwise it will be masked.
6	le4	Level/edge triggered. If set, the interrupt will be edge-triggered, otherwise level sensitive.
5	pl4	Polarity If set, the corresponding interrupt will be active high (or edge-triggered on positive edge). Otherwise, it will be active low (or edge-triggered on negative edge).
4..0	isel4	I/O port select. The value of this field defines which I/O port (0 31) should generate parallel I/O port interrupt 4.

## 15.11 PCI Registers

The PCI registers are located between 0x80000100 and 0x800002FC. Within this range, any address not shown in the following list shall neither be written nor read.

**Table 15-60. PCI Device Identification Register 1 PCIID1**

**Address:** 0x80000100

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
device id																vendor id															
r																r															
0x1202																0x1438															

Bit Number	Mnemonic	Description
31..16	device id	This field identifies the particular device.
15..0	vendor id	This field identifies the manufacturer of the device (ATMEL).

**Table 15-61. PCI Status & Command Register – PCISC**

**Address:** 0x80000104

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

r	r	r	r	r	r	r	r	r	r	r	r	r				r	r	r	r	r	r	r	r	r	r	r	r	r	r	r	r
/	/	/	/	/		/											-	-		/		/		/							
1	1	1	1	1		1											W	W		W		W		W							
0	0	0	0	0	01	0	1	0	0	0	0	0000 0000				0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit Number	Mnemonic	Description
31	stat15	PCI Bus Parity Error Status 1 = PERR* asserted (set even if parity checking is disabled) 0 = PERR* not asserted This bit shall be cleared by writing a 1 (0 has no effect).

Bit Number	Mnemonic	Description
30	stat14	PCI Interface System Error Status 1 = PCI interface asserted SERR* 0 = PCI interface does not assert SERR* This bit shall be cleared by writing a 1 (0 has no effect).
29	stat13	Initiator Interface Termination Status 1 = initiator transaction terminated with Master Abort 0 = initiator transaction successfully terminated (if any) This bit shall be cleared by writing a 1 (0 has no effect).
28	stat12	Remote Target Termination Status 1 = initiator transaction terminated with Target Abort 0 = initiator transaction successfully terminated (if any) This bit shall be cleared by writing a 1 (0 has no effect).
27	stat11	Target Interface Termination Status 1 = remote initiator transaction terminated with Target Abort 0 = remote initiator transaction successfully terminated (if any) This bit shall be cleared by writing a 1 (0 has no effect).
26..25	stat10_9	Target Interface Selection Timing 01 = DEVSEL* is asserted with medium timing
24	stat8	Initiator Interface Parity Error Status 1 = initiator interface asserted PERR* on a read transaction or observed PERR on a write transaction and Parity Error Response is enabled (bit 6) 0 = initiator interface has not asserted nor observed PERR* on a transaction (if any), or Parity Error Response is disabled (bit 6) This bit shall be cleared by writing a 1 (0 has no effect).
23	stat7	Target Interface Fast Back-to-Back Capability 1 = the target is capable of accepting fast back-to-back transactions when the transactions are not to the same agent
22	stat6	User definable features (reserved)
21	stat5	66 MHz Capability 0 = not capable
20	stat4	Power Management Capability 0 = no New Capabilities linked list is available at offset 34h, value at that location is not relevant
19	stat3	PCI Interrupt Status (reserved, no PCI interrupts)
10	com10	Interrupt Command (reserved, no PCI interrupts)
9	com9	Initiator Interface Fast Back-to-Back Control <sup>2</sup> 1 = initiator is allowed to generate fast back-to-back transactions to different targets 0 = initiator shall only generate fast back-to-back transactions to the same target
8	com8	System Error Pin Control 1 = assert SERR* 0 = do not assert SERR* Address parity errors are reported only if this bit and bit 6 are 1.

Bit Number	Mnemonic	Description
7	com7	Address/Data Stepping Control (reserved, not applicable)
6	com6	Parity Error Response Control 1 = take the normal action when a parity error is detected 0 = set the PCI Bus Parity Error Status bit (bit 31) when an error is detected but do not assert PERR* and continue normal operation
5	com5	VGA Palette Snooping (reserved, not applicable)
4	com4	Memory Write-and-Invalidate Control 1 = initiator may generate the Memory Write and Invalidate command 0 = use the Memory Write command instead
3	com3	Special Cycles Control (reserved, not applicable)
2	com2	PCI Initiator Control 1 = PCI initiator enabled 0 = PCI initiator disabled <sup>3</sup> .
1	com1	Target Memory Command Response Control 1 = target interface is allowed to respond to Memory Space accesses 0 = target interface does not respond to Memory Space accesses
0	com0	Target I/O Command Response Control 1 = target interface is allowed to respond to I/O Space accesses 0 = target interface does not respond to I/O Space accesses

Note: 1. Read-only bit in PCI Satellite mode (SYSEN\* = 1), reflects what the remote Host-Bridge sees and controls when driving the PCI interface through PCI configuration transactions.

Note: 2. Whatever the value of this bit, the PCI interface does not allow to generate fast back-to-back transactions.

**Caution:** 3. a memory-mapped PCI transaction shall not be initiated while the PCI initiator is disabled or the processor will stall.

**Table 15-62. PCI Device Identification 2 PCIID2**

**Address:** 0x80000108

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
class code																revision id															
r																r															
0x0B4000																0x02															

Bit Number	Mnemonic	Description
31..8	class code	The Class Code register is read-only and is used to identify the generic function of the device and, in some cases, a specific register-level programming interface. The register is broken into three byte-size fields. The upper byte (at offset 0Bh) is a base class code which broadly classifies the type of function the device performs. The middle byte (at offset 0Ah) is a sub-class code which identifies more specifically the function of the device. The lower byte (at offset 09h) identifies a specific register-level programming interface (if any) so that device independent software can interact with the device. The value 0x0B4000 commonly stands for a processor device.
7..0	revision id	This register specifies a device specific revision identifier. The value is chosen by the vendor. Zero is an acceptable value. This field should be viewed as a vendor defined extension to the Device ID.

**Table 15-63. PCI Bist & Header Type & Latency & Cacheline Size Register – PCIBHLC Address= 0x8000010C**

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
bist								header type								latency timer				cacheline size											
r								r								r/w <sup>1</sup>				r				r/w <sup>1</sup>							
0000 0000								0000 0000								0000 00				00				0000 0000							

Bit Number	Mnemonic	Description
31..24	bist	Built-In Self Test (BIST) A value of 0 indicates there is no support for this feature.
23..16	header type	Header Type A value of 0 indicates this is a single-function interface which implements type 00h Configuration Space Header.
15..8	latency timer	Latency Timer Specifies the value of the latency timer for this bus master (in units of PCI bus clocks).

Bit Number	Mnemonic	Description
7..0	cacheline size	<p>Cacheline Size</p> <p>Specifies the system cacheline size (in units of 32-bit words). Used by master devices to determine whether to use Read, Read Line or Read Multiple commands for accessing memory.</p> <p>Used by slave devices that want to allow memory bursting using cacheline wrap addressing mode to know when a burst sequence wraps to the beginning of the cacheline.</p>

Read-only bit in PCI Satellite mode (SYSEN\* = 1), reflects what the remote Host-Bridge sees and controls when driving the PCI interface through PCI configuration transactions.

**Table 15-64. Memory Base Address Register 1 MBAR1**

r								r								r								r/w <sup>1</sup>							
0000 0000								0000 0000								0000 0000								0000 0000							

Bit Number	Mnemonic	Description
31..24	max_lat	Maximum Latency Specifies how often the processor needs to gain access to the PCI bus. (in units of 0.25 microseconds assuming a 33 MHz clock). A value of 0 indicates there are no major requirements for this setting.
23..16	min_gnt	Minimum Grant Specifies how long a burst period is needed (in units of 0.25 $\mu$ s assuming a 33 MHz clock). A value of 0 indicates there are no major requirements for this setting.
15..8	int_pin	Interrupt Pin Indicates which interrupt pin the processor uses. Value not relevant (PCI interrupts are not implemented).
7..0	int_line	Interrupt Line Specifies which input of the system interrupt controller the interrupt pin is connected to. Value not relevant (PCI interrupts are not implemented).

Note: 1. Read-only bit in PCI Satellite mode (SYSEN\* = 1), reflects what the remote Host-Bridge sees and controls when driving the PCI interface through PCI configuration transactions.

**Table 15-71. PCI Initiator Retry & TRDY\* – PCIIRT**

**Address:** 0x80000140

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
reserved																retry						trdy									
r																r/w <sup>1</sup> .						r/w <sup>1</sup> .									
0																0x80						0x80									

Bit Number	Mnemonic	Description
15..8	retry	Maximum number of retries the PCI initiator attempts.
7..0	trdy	Maximum number of PCI clock cycles the PCI initiator waits for TRDY* .

Note: 1. Read-only bit in PCI Satellite mode (SYSEN\* = 1), reflects what the remote Host-Bridge sees and controls when driving the PCI interface through PCI configuration transactions.

**Table 15-72. PCI Configuration Byte-Enable – PCICBE**

**Address:** 0x80000144

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
reserved																												ben			
r																												r/w			
0000 0000 0000 0000 0000 0000 0000																												0000			

Bit Number	Mnemonic	Description
3..0	ben	Byte write enables to the PCI configuration registers (0x80000100 to 0x80000140): 0 = enabled 1 = disabled A byte enable pattern, once programmed, applies to all subsequent writes until it is changed.

Each of the 4 bits is assigned to one 8-bit lane:

- bit ben[3] is applied to Byte 3, the most-significant byte (MSB)
- bit ben[2] is applied to Byte 2
- bit ben[1] is applied to Byte 1
- bit ben[0] is applied to Byte 0, the least-significant byte (LSB)

**Table 15-73. PCI Initiator Start Address – PCISA**

**Address:** 0x80000148

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
stad																															
r/w																															
XXXX XXXX XXXX XXXX XXXX XXXX XXXX XXXX																															

Bit Number	Mnemonic	Description
31..0	stad	PCI start address for PCI initiator transactions in DMA mode.

**Table 15-74. PCI DMA Configuration Register – PCIDMA**

**Address:** 0x80000150

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
reserved																			d	cmd			wcnt								
r																			r / w	r/w			r/w								
0000 0000 0000 0000 000																			0	xxxx			xxxx xxxx								

Bit Number	Mnemonic	Description
11..8	cmd	Command PCI command to use in transaction. Please refer to section 3.1.1 "Command Definition" of the PCI 2.2 specification for command details.
7..0	wcnt	Word Count Number of words to transfer during the DMA burst (1 to 255).

Note: Writing to this register effectively initiates the PCI transfer when the PCI core is configured for DMA mode.

**Table 15-75. PCI Initiator Status Register – PCIIS**

**Address:** 0x80000154

Bit Number	Mnemonic	Description
12	sys	SYSEN* Pin Status 0 = Host mode 1 = Satellite mode
11..8	dmas	DMA State (0000 = idle)

Bit Number	Mnemonic	Description
7	act	PCI Initiator Active 1 = a PCI data transfer is on-going or has been requested 0 = no PCI data transfer on-going or requested
6	xff	MXMT Transmit FIFO Full 1 = transmit FIFO full 0 = transmit FIFO not full
5	xfe	MXMT Transmit FIFO Empty 1 = transmit FIFO empty 0 = transmit FIFO not empty
4	rfe	MRCV Receive FIFO Full 1 = receive FIFO empty 0 = receive FIFO not empty
3..0	cs	Controller State (0000 = idle)

**Table 15-76. PCI Initiator Configuration – PCIIC**

**Address:** 0x80000158

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
w <sup>1</sup>																															
reserved																							cmd	reserved			mod				
r																							r/w	r			r / w				
0000 0000 0000 0000 0000 0000																							01	00000			0				

Bit Number	Mnemonic	Description
7..6	cmd	Most-significant bits of the PCI command used in memory-mapped PCI transactions <sup>2</sup> : 00 = I/O read or I/O write 01 = Memory Read or Memory Write 10 = Configuration Read or Configuration Write 11 = Memory Read Line or Memory Write and Invalidate
0	mod	PCI Interface Mode 1 = Memory-Mapped / DMA <sup>3</sup> 0 = PCI initiator disabled

Note: 1. Writing the whole register with all-1s (0xFFFFFFFF) resets the interface: flush FIFOs, reset byte-enables, reset command to Memory Read/Write and terminate any memory-mapped transaction; any active DMA burst is terminated with an initiator internal error (PCIITP.iier = 1).

Note: 2. The least-significant bits depend on the instruction type that initiated the memory-mapped PCI transaction (load = 10, store = 11).

**Caution:** 3. a memory-mapped PCI transaction shall not be initiated while the PCI initiator is disabled (PCISC.com2 = 0) or the processor will stall.

**Table 15-77. PCI Target Page Address Register – PCITPA**

**Address:** 0x8000015C

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
tpa1								reserved								tpa2								reserved							
r/w								r								r/w								r							
0x40								0x00								0x90								0x00							

Bit Number	Mnemonic	Description
31..24	tpa1	Target Page Address for MBAR1 Specifies the most significant byte of the local memory address <sup>1</sup> where the PCI target Memory Base Address Register 1 is mapped (defaults to the RAM area).
15..8	tpa2	Target Page Address for MBAR2 Specifies the most significant byte of the local memory address <sup>2</sup> where the PCI target Memory Base Address Register 2 is mapped (defaults to the DSU area).
n/a	tpa3 <sup>3</sup>	Target Page Address for IOBAR3 The most significant 22 bits of the local memory address <sup>3</sup> where the PCI target IO Base Address Register 3 is mapped in local memory (defaults to the REGISTER area). This value is not exposed and is not programmable (built-in, 1000000000000000000000).

Note: 1. Assuming TPA1 is the full 32-bit address:  $TPA1 = tpa1 * 2^{24}$ . TPA1 is a pointer to a 16 Mbytes area.

Note: 2. Assuming TPA2 is the full 32-bit address:  $TPA2 = tpa2 * 2^{24}$ . TPA2 is a pointer to a 16 Mbytes area.

Note: 3. Assuming TPA3 is the full 32-bit address:  $TPA3 = tpa3 * 2^{10} = 0x80000000$ . TPA3 is a pointer to a 1024 bytes / 256 words area.

**Address:** 0x80000160

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0						
reserved																							dld	rfpe	xff	xfe	rfe	cs									
r																							r/w <sub>1</sub>	r/w	r/w <sub>1</sub>	r/w <sub>1</sub>	r/w <sub>1</sub>	r/w <sup>1</sup> .									
0000 0000 0000 0000 0000 000																							0	0	0	1	1	0000									

Bit Number	Mnemonic	Description
8	dld	Delayed Read Automatically asserted by the PCI core during a long delayed read to prevent the on-going read from being overwritten by a subsequent write request (information provided for debug purpose only). This bit is cleared by writing a 1 (a 0 has no effect).
7	rfpe	TRCV Receive FIFO parity error 0 = Do not save data with parity error 1 = Ignore any parity error and save data anyway (generation of the perr status bit and assertion of a parity error interrupt is not affected)
6	xff	TXMT Transmit FIFO Full 1 = transmit FIFO full 0 = transmit FIFO not full Writing this bit with a 1 ends the transaction with a target abort (a 0 has no effect).
5	xfe	TXMT Transmit FIFO Empty 1 = transmit FIFO empty 0 = transmit FIFO not empty Writing this bit with a 1 flushes the transmit FIFO (a 0 has no effect).
4	rfe	TRCV Receive FIFO Empty 1 = receive FIFO empty 0 = receive FIFO not empty Writing this bit with a 1 flushes the receive FIFO (a 0 has no effect).
3..0	cs	Controller State (0000 = idle) Writing this nibble with all-1s (0xF) resets the state machine (any other value has no effect).

Note: 1. This (group of) bit(s) has a specific action when written with a (group of) 1(s).

**Table 15-79. PCI Interrupt Enable Register – PCIITE**

2	tber	Target byte-enable error <sup>1</sup> 1 = enable 0 = mask
1	tper	Target parity error <sup>1</sup> 1 = enable 0 = mask
0	serr	SERR* signal asserted on the PCI bus <sup>1</sup> 1 = enable 0 = mask

Note: 1. See the corresponding field in PCIITP for a complete description.

**Table 15-80. PCI Interrupt Pending Register – PCIITP**

**Address:** 0x80000168

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
reserved																							dm	af	ier	ifer	iper	tier	tber	tper	serr
r																							r/w <sup>1</sup>								
0000 0000 0000 0000 0000 0000																							0	0	0	0	0	0	0	0	0

Bit Number	Mnemonic	Description
7	dm <sup>a</sup> f	DMA finished 1 = pending 0 = not pending
6	ier	Initiator internal error <sup>2</sup> . 1 = pending 0 = not pending The PCI initiator internally faced a situation that prevented normal completion of the programmed transaction.
5	ifer	Initiator fatal error 1 = pending 0 = not pending The PCI initiator reported an address parity error or a transaction abort.
4	iper	Initiator parity error 1 = pending 0 = not pending The PCI initiator reported data with parity error on a read or write transaction.
3	tier	Target internal error <sup>3</sup> . 1 = pending 0 = not pending The PCI target internally faced a situation that prevented normal completion of the programmed transaction.
2	tber	Target byte-enable error 1 = pending 0 = not pending The PCI target received data with unsupported byte-enables.
1	tper	Target parity error 1 = pending 0 = not pending The PCI target received data with parity error.
0	serr	SERR* signal asserted on the PCI bus 1 = pending 0 = not pending

Note: 1. Each bit is cleared when written with a 1 (writing a 0 has no effect).

Note: 2. An initiator internal error is reported on the following events: initiator busy or not ready (already active DMA transfer), local memory 1 KB address boundary reached (DMA), attempt to transfer data to/from the PCI mapped-address area (DMA), invalid data read or written (timeout), interface reset during an active DMA transfer...

Note: 3. A target internal error is reported on the following events: invalid data read or written (timeout).

**Table 15-81. PCI Interrupt Force Register – PCIITF**

**Address:** 0x8000016C

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Bit Number	Mnemonic	Description
7	dmaf	DMA finished <sup>3</sup> 1 = forced 0 = cleared <sup>4</sup> .
6	ier	Initiator internal error <sup>3</sup> 1 = forced 0 = cleared <sup>4</sup> .
5	ifer	Initiator fatal error <sup>3</sup> 1 = forced 0 = cleared <sup>4</sup> .
4	iper	Initiator parity error <sup>3</sup> 1 = forced 0 = cleared <sup>4</sup> .
3	tier	Target internal error <sup>3</sup> 1 = forced 0 = cleared <sup>4</sup> .
2	tber	Target byte-enable error <sup>3</sup> 1 = forced 0 = cleared <sup>4</sup> .
1	tper	Target parity error <sup>3</sup> 1 = forced 0 = cleared <sup>4</sup> .

Bit Number	Mnemonic	Description
0	serr	SERR* asserted on the PCI bus <sup>3</sup> . 1 = forced 0 = not forced

Note: 1. This is a write-only register, reading this register always yields the contents of PCIITP.

Note: 2. A PCI interrupt is generated on the write operation itself.

Note: 3. See the corresponding field in PCIITP for a complete description.

Note: 4. Writing a 0 clears the corresponding bit in PCIITP rather than not forcing it.

## 15.12 DSU Registers

**Caution:** This section is provided for information purpose only.

**Caution:** As its name clearly states, the Debug Support Unit is exclusively meant for debugging purpose. None of the DSU features shall ever be used in the final application where the DSU shall be turned into an inactive state (DSUEN, DSURX and DSUBRE tied to a permanent low level).

**Table 15-84. DSU Control Register – DSUC**

**Address:** 0x90000000

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

000			x xxxx xxxx									0	0	0	0	0	p	p	0	0	p	p	0	p	0	p	p	0	0	x	0

Bit Number	Mnemonic	Description
28..20	dcnt	Trace buffer delay counter
19	re	Reset error mode If set, will clear the error mode in the processor. This is a write-only bit, always reads as a 0.
18	dr	Debug mode response If set, the DSU communication link will send a response word when the processor enters debug mode
17	lr	Link response If set, the DSU communication link will send a response word after an AHB transfer.
16	ss	Single step If set, the processor will execute one instruction and then return to debug mode.
15	pe	Processor error mode returns 1 on read when processor is in error mode else return 0.
14	ee	Value of the DSUEN signal (read-only)
13	eb	Value of the DSUBRE signal (read-only)
12	dm	Debug mode If set, indicates the processor has entered debug mode (read-only).

Bit Number	Mnemonic	Description
11	de	<p>Delay counter enable</p> <p>If set, the trace buffer delay counter will decrement for each stored trace. This bit is set automatically when an DSU breakpoint is hit and the delay counter is not equal to zero.</p>
10	bz	<p>Break on error traps</p> <p>If set, will force the processor into debug mode on all but the following traps: <code>privileged_instruction</code>, <code>fpu_disabled</code>, <code>window_overflow</code>, <code>window_underflow</code>, <code>asynchronous_interrupt</code>, <code>ticc_trap</code>.</p> <p>During reset, this bit is initialized with the value of the DSUBRE signal.</p>
9	bx	<p>Break on trap</p> <p>If set, will force the processor into debug mode when any trap occurs.</p>
8	bd	<p>Break on DSU breakpoint</p> <p>If set, will force the processor into debug mode when an DSU breakpoint is hit.</p> <p>During reset, this bit is initialized with the value of the DSUBRE signal.</p>
7	bn	<p>Break now</p> <p>If set, will force the processor into debug mode provided bit 5 (<code>bw</code>) is also set. If cleared, the processor will resume execution.</p> <p>During reset, this bit is initialized with the value of the DSUBRE signal.</p>
6	bs	<p>Break on S/W breakpoint</p> <p>If set, will force the processor into debug mode when a breakpoint instruction (<code>ta 1</code>) is executed.</p>
5	bw	<p>Break on IU watchpoint</p> <p>If set, debug mode will be forced on a IU watchpoint (trap <code>0xb</code>).</p> <p>During reset, this bit is initialized with the value of the DSUBRE signal.</p>
4	be	<p>Break on error</p> <p>If set, will force the processor into debug mode when the processor would have entered error mode.</p> <p>During reset, this bit is initialized with the value of the DSUBRE signal.</p>
3	ft	<p>Freeze timers</p> <p>If set, the scaler in the timer unit will be stopped during debug mode to preserve the time for the software application.</p>
2	bt	<p>Break on trace freeze</p> <p>If set, will generate a DSU break condition on trace freeze.</p>
1	dm	<p>Delay counter mode</p> <p>In mixed tracing mode, setting this bit will cause the delay counter to decrement on AHB traces. If reset, the delay counter will decrement on instruction traces</p>
0	te	<p>Trace enable.</p> <p>If set, the trace buffer is enabled.</p>

Bit Number	Mnemonic	Description
17..16	ab	Scaler reload value
15..0	rv	Scaler reload value

Note: The following equations shall be used to calculate the scaler value or the baudrate value based on the clock frequency:

$$scaler_{rv} = \frac{sdclk_{freq}}{baudrate \times 8} - 1$$

$$baudrate = \frac{sdclk_{freq}}{8 \times (scaler_{rv} + 1)}$$

## 15.13 Reconfigurable unit register description

The ATF697FF reconfigurable unit (AT40K series) devices have a 32-bit control register that is written at the beginning of a configuration download. These bits control various configuration sequence parameters. All bits are set to 0 during a configuration clear cycle. In parallel modes, byte 0 is loaded first. In serial modes, bit-31 is loaded first. The control register settings are made in the FPGA Designer IDS Software Options section:

- Go to the Options menu on the IDS (Figaro) main window and select Options.
- Choose AT40K Bitstream from the topics list<sup>1</sup>.

**Caution:** IDS uses names "B0" ~ "B31" for "CR0" ~ "CR31" for the Control Register.

**Table 15-95. Control Registers**

### CR0 – Mode 6 Address Counter

- 0 = Reset Address Counter
- 1 = Retain Address Counter

CR0 controls the value of the Mode 6 device's memory address counter after each configuration sequence. The default resets the address up-counter to 000000 after each configuration download is completed. When this bit is set, the memory address counter retains its last value. This allows multiple designs to be stored sequentially in an external memory device for use in reconfigurable systems.

**Caution:** The mode 6 is not available in the ATF697FF product. Hence, the CR0 shall be always set to 0.

### CR1 Not used (ignored)

### CR2 Cascading

- 0 = Enable Cascading
- 1 = Disable Cascading

CR2 controls the operation of the dual-function I/O CSOUT. When CR2 is set, the CSOUT pin is not used by the configuration during downloads.

### CR3 Check

- 0 = Check Function enabled
- 1 = Check Function disabled

CR3 controls the operation of the CHECK pin and enables the Check Function. When CR3 is set, the CHECK pin is not used by the configuration during downloads.

### CR4 Memory Lockout

- 0 = Memory Lockout disabled
- 1 = Memory Lockout enabled

CR4 is the Security Flag and controls the writing and checking of configuration memory during any subsequent configuration download. When CR4 is set, any subsequent configuration download initiated by the user, whether a normal download or a CHECK function download, causes the INIT pin to immediately activate. CON is released, and no further configuration activity takes place. The download sequence during which CR4 is set is NOT affected. The Control Register write is also prohibited, so bit CR4 may only be cleared by a power-on-reset or manual reset.

#### **CR5 JTAG**

- 0 = JTAG enable
- 1 = JTAG disable

**Caution:** The JTAG is not available in the ATF697FF product. Hence, the CR5 shall be always set to '1'.

#### **CR6 – OTS**

- 0 = OTS disabled
- 1 = OTS enabled

Setting CR6 makes the OTS pin an input which controls the global tri-state control for all user I/O.

#### **CR7 – Parallel bus width**

- 0 = 8-bit data access
- 1 = 16-bit (Wide) data access

CR7 is the Wide data control bit. Setting this bit immediately enables bits D8:D15 of the configuration interface as inputs for all parallel modes (2 and 6). All writes and checks of configuration memory are subsequently performed by 16 bits. CR7 is ignored in serial modes (0, 1 and 7).

**Caution:** The parallel modes are not available in the ATF697FF product. Hence, CR7 is ignored.

#### **CR8 Recurrent checksum**

- 0 = no recurrent checksum
- 1 = activates the recurrent checksum

If configured in Master mode 0, it is mandatory to activate CR13 bit when using CR8 bit in order to clock the CSIC feature. For all other modes, CCLK shall be provided from the external.

#### **CR9 Function bad\_state**

- 0 = no function bad\_state
- 1 = enables the function bad\_state during the FPGA configuration

#### **CR10 Not used (ignored)**

#### **CR11 Not used (ignored)**

#### **CR12 Not used (ignored)**

#### **CR13 – CCLK operation**

- 0 = CCLK normal operation
- 1 = CCLK continues after configuration

Setting bit CR13 allows the CCLK pin to continue to run after configuration download is completed. This bit is valid for Master Mode only.

#### **CR14/CR15 – CCLK Frequency**

- 00 = 1 MHz

- 01 = 4 MHz
- 10 = 8 MHz
- 11 = 16 MHz

Bits CR14 and CR 15 speed up the internal oscillator and allow the Master Mode to drive CCLK at 1, 4, 8 or 16 MHz. As soon as the values of these bits are sampled by the FPGA, the CCLK frequency is increased consequently.

#### **CR16/CR23 – GCK enable**

- 0 = GCK 0:7 always enabled
- 1 = GCK 0:7 disabled during configuration download.

Setting CR16:C23 allows the user to disable the input buffers driving the global clocks. The clock buffers are enabled and disabled synchronously with the rising edge of the respective GCLK signal, and stop in a High (“1”) state. Setting one of these bits disables the appropriate GCLK input buffer only and has no effect on the connection from the input buffer to the FPGA array.

#### **CR24/CR27 – FCK enable**

- 0 = FCK 0:3 always enabled
- 1 = FCK 0:3 disabled during configuration download.

Setting CR24.C27 allows the user to disable the input buffers driving the fast clocks. The clock buffers are enabled and disabled synchronously with the rising edge of the respective FCLK signal, and stop in a High (“1”) state. Setting one of these bits disables the appropriate FCLK input buffer only and has no effect on the connection from the input buffer to the FPGA array.

#### **CR28 Reserved**

**Caution:** must be '0'

#### **CR29 Not used (ignored)**

#### **CR30 – Global Set/Reset**

- 0 = Global set/reset normal
- 1 = Global set/reset active (Low) during configuration

CR30 allows the Global set/reset hold the core DFFs in set/reset during any configuration download. The Global set/reset net is released at the end of configuration download on the rising edge of CON.

#### **CR31 – IO tristate**

- 0 = Disable I/O tri-state
- 1 = I/O tri-state during configuration

CR31 forces all user defined I/O pins to go tri-state during configuration download. tri-state is released at the end of configuration download on the rising edge of CON.

## 17. Electrical characteristics

### 17.1 Absolute maximum ratings

Operating Temperature .....	-55 °C to +125 °C
Storage Temperature .....	-65 °C to +150 °C
Maximum junction temperature (T <sub>J</sub> ) .....	175°C
Thermal resistance junction to case (R <sub>jc</sub> ) .....	0.54°C/W
Voltage on Core .....	-0.3 V to + 2.0 V
Voltage on I/O .....	-0.3 V to + 4:0 V
DC current PROC_VCC33 (PROC_VDD18) and PROC_VSS33 (PROC_VSS18) Pins.....	200 mA
Input Voltage on I/O pins with respect to Ground .....	-0.5 V to +4 V
DC current per I/O pins .....	40 mA
ESD	
(HBM).....	(class 2) 2000 to 3999 V
(CDM).....	(class C4) (750<CDM ESD sensitivity level <1000 V)

Stresses at or above those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## 17.2 DC characteristics

### 17.2.1 DC characteristics

The external shared pins are A[0:27], D[0:31], ROMS[0:1],IOS,RAMS[0:4],RAMOE[0:4], OE, WRITE, READ, SDCLK, BEXC, BRDY, RWE[0:3] & GPIO[0:7].

**Table 17-1. DC characteristics**

Symbol		Parameter	Min	Typ	Max	Unit	Test Conditions
PROC_VCC33		I/O Power Supply Voltage	3.0	3.3	3.6	V	
PROC_VDD18		Core Power Supply Voltage	1.65	1.8	1.95	V

IICS	Cold sparing leakage input current		-1		1	μA	VCC33 = PROC_VSS FPGA_VSS  Vin = PROC_VSS to PROC_VCC33 (max) FPGA_VSS to FPGA_VCC33(max)

IOCS	Cold sparing leakage output current	-1	1	$\mu\text{A}$	VCC33 = PROC_VSS FPGA_VSS  Vin = PROC_VSS to PROC_VCC33 (max) FPGA_VSS to FPGA_VCC33(max)
------	-------------------------------------	----	---	---------------	---

Note: 1. This value is not tested and for information only

Note: 2. This measurement is done with PROC On and FPGA off.

## 17.2.2 LVDS AC/DC characteristics

Table 17-2. LVDS Driver DC/ AC Characteristics

Symbol	Parameter	Test Condition	Min	Max	Units	Comments
VOD	Output differential voltage	Rload = 100 $\Omega$	247	454	mV	see Figure below
VOS	Output voltage offset	Rload = 100 $\Omega$	1125	1375	mV	see Figure below
\DeltaVOD	Change in VOD between "0" and "1"	Rload = 100 $\Omega$	0	50	mV	–
\DeltaVOS	Change in VOS between "0" and "1"	Rload = 100 $\Omega$	0	50	mV	–
ISA, ISB	Output current	Drivers shorted to ground or VCC	1	6.2	mA	
ISAB	Output current	Drivers shorted together	2.6	4.8	mA	–
F Max.	Maximum operating frequency	VCC = 3.3V $\pm$ 0.3V	–	200	MHz	Consumption 20.9 mA
Clock	Clock signal duty cycle	Max. frequency	45	55	%	–
Tfall	Fall time 80-20%	Rload = 100 $\Omega$	445	838	ps	see Figure below
Trise	Rise time 20-80%	Rload = 100 $\Omega$	445	841	ps	see Figure below
Tp	Propagation delay	Rload = 100 $\Omega$	1120	2120	ps	see Figure below
Tsk1	Duty cycle skew	Rload = 100 $\Omega$	0	80	ps	–
Tsk2	Channel to channel skew (same edge)	Rload = 100 $\Omega$	0	50	ps	–

Figure 17-1. Test Termination Measurements

$$V_{OS} = \frac{(V_A + V_B)}{2}$$

Figure 17-2. Rise and Fall time measurements

Table 17-3. LVDS Receiver DC/ AC Characteristics

Symbol	Parameter	Test Condition	Min	Max	Units	Comments
VID	Input differential voltage	-	200	600	mV	-
VCM	Input offset range	-	400	2000	mV	-
Tp	Propagation delay	Cout = 50 pF, VDD = 3.3V ± 0.3V	0.7	2.4	Ns	-
Tskew	Duty cycle distortion	Cout = 50 pF	-	500	ps	-

## 17.3 Cold sparing

Cold sparing capability of the IOs allows to be electrically connected to a bus while its power supply remains in the range [VSS-300mV/VSS+300mV], this without any risk of damage for the device. Cold-sparing allows a redundant spare to be electrically connected but unpowered until needed.

For applications requiring high reliability, the capability to use of a redundant device is a key feature. Cold sparing availability on the ATF697FF makes the product especially suitable for high reliability systems.

The cold sparing feature is available for:

- All the General Purpose I/Os of the reconfigurable part
- All the LVDS I/Os of the reconfigurable part
- All the inputs of the processor part

They present a high input impedance when unpowered [VSS-300mV / VSS+300mV] and exhibit a negligible leakage current if exposed to a non-null input voltage at that time.

Remarks: All the internal PCI pins are required to be clamped to both the ground and power rails to comply with the PCI Specification. However, they are cold-sparing as the clamp to PROC\_VCC33 is removed when unpowered (and clamped to VCC33 when powered). The clamp to PROC\_VSS33 is always present whatever the power condition.

## 17.4 Power sequencing

### 17.4.1 Global sequencing

The ATF697FF is based on Atmel ATC18RHA 0.18  $\mu$ m CMOS process. When the ATF697FF needs to be powered "on/off" while other circuits in the application are still powered, the recommended power "on/off" sequence is:

- power-up: first power PROC\_VCC33 (I/O) & FPGA\_VCC33 (I/O), and then power PROC\_VDD18 (Core) & FPGA\_VDD18 (Core).
- power-down: first unpower PROC\_VDD18 (Core) & FPGA\_VDD18 (Core), and then unpower PROC\_VCC33 (I/O) & FPGA\_VCC33 (I/O).

It is also recommended to stop all activity during these phases as a bi-directional could be in an undetermined state (input or output mode) and create bus contention.

### 17.4.2 ATF697FF reconfigurable unit : Power-On Management

ATF697FF reconfigurable unit has an inrush current during power-up phase that need to be considered with care by the board designer in order to adjust his power consumption budget. This inrush current is due to indeterminate states of configuration memory cells not already initialized which create an excessive leakage current.

The ATF697FF reconfigurable unit design has been optimized in order to minimize the leakage causing the inrush current.

Figure 17-3. Inrush current

The following table shows the ATF697FF reconfigurable unit inrush characteristics

Table 17-4. Inrush Current

VDD=1.8V	$I_{VDD}$ (A)	
	Worst Case	Typical
125°C	2	1.8
90°C	2	1.7
25°C	2	1.7
-30°C	2	1.6
-55°C	2	1.5

Since the inrush current can reach more than 1.8A, we recommend users to dimension their power supply in order to be able to provide at least 2 Amps peak current.

## 17.5 Power Consumption

### 17.5.1 Power consumption of processor part

The power consumption is the sum of three basic contributions:  $P = P_{Core} + P_{I/O} + P_{PCI}$

$P_{Core}$  represents the contribution of the internal activity.

$P_{I/O}$  represents the contribution of the IO pads (except the PCI bus) and associated output load current .

$P_{PCI}$  represents the contribution of the PCI pads and associated output load current.

**Table 17-5. Power Dissipation**

Conditions	Typical <sup>1</sup>			Worst-Case <sup>2</sup>		
	P <sub>Core</sub>	P <sub>I/O</sub>	P <sub>PCI</sub>	P <sub>Core</sub>	P <sub>I/O</sub>	P <sub>PCI</sub>
Power (in W)	0.5	0.2	0.1	0.7	0.3	0.2

Note: 1. Typical conditions: 25°C, 1.8V core, 3.3V I/O, 100 MHz, high I/O and core activity.

Note: 2. Worst-case conditions: -55°C, 1.95 V core, 3.6V I/O, 100 MHz, high I/O and core activity.

### 17.5.2 Power consumption of reconfigurable unit

The worst case consumption for the reconfigurable unit part is during power on. Please see the corresponding section for details.

## 17.6 AC Characteristics

The ATF697FF implements a single event transient (SET) protection mechanism. The influence of this protection is reflected by the timing figures presented in the following tables.

The following tables show the timing figures for the natural and maximum skew conditions.

### 17.6.1 Natural Skew

#### 17.6.1.1 Test Conditions

Natural Skew

Temperature range: -55°C to 125°C

Voltage range:

- I/O: 3.3V ± 0.30V
- Core: 1.8V ± 0.15V

Output load: 50 pF

Voltage threshold Test condition:  $V_{cc}/2$

**Table 17-6. AC Characteristics Natural Skew**

Parameter	Min (ns)	Max (ns)	Comment	Reference edge ('+' for rising edge)
t1	10		CLK period with PLL disabled	
t1_p <sup>1</sup>	40	50	CLK period with PLL enabled	
t2	4.5		CLK low or high pulse width PLL disabled	
t2_p	18		CLK low or high pulse width PLL enabled	
t3	10		SDCLK period	
t4	3	8	SDCLK output delay PLL disabled	CLK
t5		10.00E+07	PLL setup time	
t6	1*t3		PROC_RESET* low pulse width <sup>2</sup>	
t10	1.5	8	A[27:0] output delay	SDCLK +
t11	2	8.5	D[31:0] and CB[7:0] output delay	SDCLK +
t12	4		D[31:0] and CB[7:0] setup time	SDCLK +
t13	0		D[31:0] and CB[7:0] hold time during load/fetch	SDCLK +
t14	0	9	D[31:0] and CB[7:0] hold time during write <sup>3</sup> .	SDCLK +
t15	1	7	OE* , READ and WRITE* output delay	SDCLK +
t16	2	5.5	ROMS* [1:0] output delay	SDCLK +
t17	1.5	6	RAMS* [4:0], RAMOE* [4:0] and RWE* [3:0]output delay	SDCLK +
t18	2	5.5	IOS* output delay	SDCLK +
t19	5		BRDY* setup time	SDCLK +
t20	0		BRDY* hold time	SDCLK +
t21	2	8	SDCAS* output delay	SDCLK +
t22	1.5	8.5	SDCS* [1:0], SDRAS* , SDWE* and SDDQM [3:0]output delay	SDCLK +
t23	4.5		BEXC* setup time	SDCLK +
t24	0		BEXC* hold time	SDCLK +
t25	1.5	10	GPIO[15:0] output delay	SDCLK +
t26	5		GPIO[15:0] setup time	SDCLK +
t27	0		GPIO[15:0] hold time during load	SDCLK +

t28	2.5		GPIO[15:0] hold time during write <sup>3</sup>	SDCLK +
-----	-----	--	--	---------

Note: 1 Not tested, guaranteed by design.

Note: 2. Although the processor is being reset asynchronously, this timing is a minimum requirement to guarantee a proper reset of the processor: a glitch of any shorter duration may lead to an unpredictable behavior.

Note: 3. The given timing indicates when the buffer is not driving any level on the bus. This timing is independent of the capacitive load.

## 17.6.2 Maximum Skew

### 17.6.2.1 Test Conditions

Maximum Skew Programmed

Temperature range: -55°C to 125°C

Voltage range:

- I/O: 3.3V ± 0.30V
- Core: 1.8V ± 0.15V

Output load: 50pF

Voltage threshold Test condition:  $V_{cc}/2$

**Table 17-7. AC Characteristics Maximum Skew**

Parameter	Min (ns)	Max (ns)	Comment	Reference edge ( '+' for rising edge)
t1	12		CLK period with PLL disabled	
t1_p <sup>1</sup>	48	50	CLK period with PLL enabled	
t2	5.4		CLK low or high pulse width PLL disabled	
t2_p	21		CLK low or high pulse width PLL enabled	
t3	10		SDCLK period	
t4	3	8	SDCLK output delay PLL disabled	CLK
t5		10.00E+07	PLL setup time	
t6	1*t3		PROC_RESET* low pulse width <sup>1</sup>	
t10	1.5	9	A[27:0] output delay	SDCLK +
t11	2	9.5	D[31:0] and CB[7:0] output delay	SDCLK +
t12	4		D[31:0] and CB[7:0] setup time	SDCLK +
t13	0		D[31:0] and CB[7:0] hold time during load/fetch	SDCLK +
t14	1	11	D[31:0] and CB[7:0] hold time during write <sup>2</sup> .	SDCLK +
t15	1	7.5	OE* , READ and WRITE* output delay	SDCLK +
t16	2	8	ROMS* [1:0] output delay	SDCLK +
t17	1.5	7	RAMS* [4:0], RAMOE* [4:0] and RWE* [3:0]output delay	SDCLK +
t18	2	7	IOS* output delay	SDCLK +
t19	5		BRDY* setup time	SDCLK +
t20	0		BRDY* hold time	SDCLK +
t21	2	10	SDCAS* output delay	SDCLK +
t22	1.5	9.5	SDCS* [1:0], SDRAS* , SDWE* and SDDQM [3:0]output delay	SDCLK +
t23	4.5		BEXC* setup time	SDCLK +
t24	0		BEXC* hold time	SDCLK +
t25	1.5	11	GPIO[15:0] output delay	SDCLK +
t26	5		GPIO[15:0] setup time	SDCLK +
t27	0		GPIO[15:0] hold time during load	SDCLK +
t28	2.5		GPIO[15:0] hold time during write <sup>2</sup>	SDCLK +

Note: 1. Although the processor is being reset asynchronously, this timing is a minimum requirement to guarantee a proper reset of the processor: a glitch of any shorter duration may lead to an unpredictable behavior.

Note: 2. The given timing applies when the buffer is not driving any level on the bus. This timing is independent of the capacitive load.

### 17.6.3 Timing Derating

The timing figures change with the capacitance load on each pin. The following table summarizes the timing derating versus the capacitance load in the whole process / voltage / temperature range.

**Table 17-8. Timing Derating (ns/pF above 50pF)**

Signal	Min	Max
A[27:0]	0.019	0.053
CB[7:0]	0.019	0.051
D[31:0]	0.019	0.051
DSUACT	0.078	0.214
DSUTX	0.078	0.214
ERROR*	0.019	0.053
IOS*	0.019	0.053
LOCK	0.039	0.107
OE*	0.019	0.053
PIO[15:0]	0.039	0.106
RAMOE*[4:0]	0.019	0.053
RAMS*[4:0]	0.019	0.053
READ	0.019	0.053
ROMS*[1:0]	0.019	0.053
RWE*[3:0]	0.019	0.053
SDCAS*	0.039	0.107
SDCLK	0.019	0.053
SDCS*[1:0]	0.039	0.107
SDDQM[3:0]	0.039	0.107
SDWE*	0.039	0.107
SRAS*	0.039	0.107
WDOG*	0.019	0.053
WRITE*	0.039	0.107

The values provided in this table are not tested, they are for information only.

**Caution:** The hypothesis taken for this calculation is to only consider the 2 two dies which constitute ATF697FF product.

## 17.7 AC parameters (reconfigurable unit)

All the timings are given at the worst case corner.

- All input I/O characteristics measured from  $V_{IH}$  of 50% of  $V_{CC}$  at the pad (CMOS threshold) to the internal  $V_{IH}$  of 50% of  $V_{CC}$ .
- All output I/O characteristics are measured as the average of  $T_{PD\text{LH}}$  and  $T_{PD\text{HL}}$  to the pad  $V_{IH}$  of 50% of  $V_{CC}$ .
- Clocks and Reset Input buffers are measured from a  $V_{IH}$  of 1.5V at the input pad to the internal  $V_{IH}$  of 50% of  $V_{CC}$ .
- Maximum times for clock input buffers and internal drivers are measured for rising edge delays only.

All the values provided here after are simulation values. They are not measured on production environment.

**Table 17-9. Propagation Delay characteristics**

Cell Function	Parameter	Path	Value	Units	Notes
IO					
Input 3.3V	$t_{PD}$	pad -> q	3.6	ns	propagation delay from pad to q, no extra delay
Input 3.3V	$t_{PD}$	pad -> q	3.7	ns	propagation delay from pad to q, extra delay 1
Input 3.3V	$t_{PD}$	pad -> q	4.1	ns	propagation delay from pad to q, extra delay 3
Input 3.3V	$t_{PD}$	pad -> q	4.6	ns	propagation delay from pad to q, extra delay 5
Output, 3.3V, slow	$t_{PD}$	a -> pad	7.1	ns	propagation delay from a to pad, 40 pF load
Output, 3.3V, medium	$t_{PD}$	a -> pad	6.2	ns	propagation delay from a to pad, 40 pF load
Output, 3.3V, fast	$t_{PD}$	a -> pad	6.0	ns	propagation delay from a to pad, 40 pF load
Output, 3.3V, slow	$t_{PD}$	oe -> pad	8.2	ns	propagation delay from oe to pad, 40 pF load
Output, 3.3V, medium	$t_{PD}$	oe -> pad	7.4	ns	propagation delay from oe to pad, 40 pF load
Output, 3.3V, fast	$t_{PD}$	oe -> pad	7.1	ns	propagation delay from oe to pad, 40 pF load

**Table 17-10. Clock – Set/Reset AC characteristics**

Function	Parameter	Path	Value	Units	Notes
Global Clocks and Set/Reset					
GCK Input pad at 3.3V	$t_{PD}$	pad -> clk	9.5	ns	delay from GCKx global clock pad to flop on the rising edge clock
FCK Input pad at 3.3V	$t_{PD}$	pad -> clk	8	ns	delay from FCKx fast clock pad to flop on the rising edge clock. Warning: Flops must be placed on first or last column of the matrix
Reset Input pad at 3.3V	$t_{PD}$	pad -> sn   rn	10	ns	delay from any pad to the set/reset flop pin

GCK input pad to output pad (3.3V, fast)	$t_{PD}$	pad -> pad	22	ns	delay from GCKx global clock pad to an output pad loaded at 40pF Warning: flop is placed close to the output pad
FCK input pad to output pad (3.3V, fast)	$t_{PD}$	pad -> pad	20	ns	delay from FCKx fast clock pad to an output pad loaded at 40pF Warning: Flops must be placed on first or last column of the matrix

Burst of SRAM Fetches with Instruction Cache and Burst enabled n wait-states

SDRAM Read (or Fetch) with Precharge Burst Length = 1; CL = 3

SDRAM Write with Precharge Burst Length = 1; CL = 3

Fetch from ROM, Read and Write from/to 32-bit I/O 0 wait-states

Fetch from ROM, Read and Write from/to 32-bit I/O n wait-states

Fetch from ROM, Read and Write from/to 32-bit I/O n wait-states + sync. BRDY\*

The timing diagrams with fetch, read and/or write operations were generated using specific instruction sequences. Considering the complex nature of the interactions within the processor (IU pipeline, memory-controller, instruction cache...), the signals waveforms found in a final application may possibly exhibit slight functional cycle variations over the proposed timing diagrams. Source code for the timing diagrams is available on request.
